The Chairman: Very well, gentlemen, then the amendment is carried, that the Company shall not be wound up.

Votes of thanks to the Chairman and Directors were passed, and the meeting separated.

Eastern Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended 30th September, 1887, to be presented to the thirty-first half-yearly ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, London, on Thursday, the 19th inst., at 1 o'clock:—

2. The revenue for the period amounted to £291,265. 13s. 3d., from which are deducted £79,936. 11s. 4d. for the ordinary expenses, and £34,102. 5s. 7d. for expenditure relating to repairs and renewals of cables, &c., during the half-year. After providing £4,465. 4s. 8d. for income-tax, there remains a balance of £172,761. 11s. 8d., to which is added £559. 3s. 2d., brought from the preceding half year, making a total available balance of £173,320. 14s. 10d.

3. From this balance there have been paid:—

	£	s.	d.
Interest on Debentures and Debenture Stock	28,538	4	9
Dividend on Preference Shares	20,384	13	8
Two interim dividends of 1¼ per cent. each on Ordinary Shares	95,000	0	0
	£143,922	18	5

leaving a balance of £29,397. 16s. 5d., which is carried forward to the next account.

4. The revenue includes £15,600 dividend for the half year upon the Company's shares in the Eastern and South African Telegraph Company, and also £384. 4s. 5d. net receipts for the half year on the shares of the Black Sea Telegraph Company belonging to this Company. The cables of these companies are in good working order.

5. With some exceptions, the several sections of the Company's cables and land lines continue in good working order; but as the Company's system is duplicated, and in some places triplicated, the interruptions do not affect the revenue.

6. The new cable from Porthcurnow to Lisbon, Gibraltar, Malta, and Zante, referred to at the last meeting, was successfully laid by the contractors, the Telegraph Construction and Maintenance Company, and opened for traffic in October last.

7. The new cable steamer "Amber," built by Messrs. Napier and Sons, Glasgow, to replace the ss. "Volta," has been launched, and will shortly be ready for service.

8. The Directors have satisfactorily completed the issue of 4 per cent. Mortgage Debenture Stock, to replace the £450,000 5 per cent. debentures which fell due on August 1 last.

9. In accordance with the provisions of the Articles of Association two of the Directors, Sir John Pender and the Marquis of Tweeddale, retire by rotation at this meeting, and being eligible offer themselves for re-election.

10. The auditors, Mr. Henry Dever and Messrs. Quilter, Welton and Co., retire, and offer themselves for re-election.

The Direct United States Cable Company (Limited).

The following is the report of the Directors for the six months ended 31st December, 1887, to be presented at the twenty-first ordinary general meeting of the Company, to be held at Winchester House, 50, Old Broad-street, on Friday, the 20th inst., at 2 p.m.:—

2. The revenue for the half year (subject to revision on settlement with the French Company), after deducting out-payments, amounted to £23,002. 17s. 6d., against £19,603. 6s. 11d. (after similar deductions) for the corresponding period of 1886, being a difference of £3,399. 10s. 7d. in favour of the half year under review.

3. The working and other expenses for the same period, including income-tax, &c., amounted to £15,864. 18s., leaving a balance of £7,137. 19s. 6d. as the net profit of the half year, making with £5,004. 0s. 6d. transferred from the reserve fund account a total of £12,142. For the corresponding half year of 1886 the working expenses and other payments amounted to £16,354. 7s. 6d.

4. Interim dividends of 2s. per share each for the quarter ended 30th September, 1887 (paid 24th October, 1887), and for the quarter ended 31st December, 1887 (payable 24th January, 1888), together amounting to £12,142, have been declared.

5. After mature consideration by the Board, the Company's cables and station were removed, during October and November last, from Torbay to Halifax (N.S.), and that portion of the short cable which lay across "Brown's Bank" was taken up and relaid in deeper water to the southward of the bank. 101 knots of new cable were required for carrying out these operations, which were successfully performed by the Telegraph Construction and Maintenance Company with their ss. "Britannia." By the changes thus made it is expected that the interests of the Company will be largely benefited, and that the costly interruptions, formerly so frequent, will probably now be avoided. The cost of the whole work, including charter of the ship and cable expended, amounted to £22,827. 5s. 10d.

6. The test action brought by the Anglo-American Telegraph Company against La Compagnie Française du Télégraphe de Paris à New York, to enforce performance of the joint-purse agreements, was heard before the Paris Tribunal of Commerce on the 12th ultimo. The decision in the case has been postponed till the 9th instant. The Directors have now the satisfaction of being able to report that the decision of the Paris Tribunal was delivered on the 9th instant, adjudging the French Company to perform the joint-purse agreements, and condemning that company to pay 2,000 francs per day, from the 1st January, 1887 (estimated at £30,000), as damages for past breaches, and further mulcting it in the costs of the action.

7. With a view of affording additional facilities to the public, a joint (branch) office has been established by the associated companies at Broome-street, New York.

Digitized by Google

8. The sixpenny tariff continues, but the progressive development in the traffic has not been maintained.

9. The Directors record with deep regret the loss they have sustained by the death of Lord Hawke, which occurred suddenly on the 5th December last. Lord Hawke had been a Director of the Company from the date of its reconstruction in 1877. The vacant seat at the Board has not been filled up.

10. The engagement of Mr. J. W. Fuller, late secretary and traffic manager, has been terminated in consequence of severe illness, to the great regret of the Board.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 6th inst. amounted to £4,491.

DIRECT UNITED STATES CABLE COMPANY.—The directors of this company have declared an interim dividend of 2s. per share free of income-tax, being at the rate of 2 per cent. per annum, for the quarter ended 31st December, 1887, such dividend to be payable on and after the 24th inst.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of December, 1887, amounted to £38,908, and to £40,539 in the corresponding period of 1886.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of December, 1887, amounted to £21,600; from 1st January to 31st December, 1887, £264,480; while for the corresponding months of 1886 and 1885 they were £258,600 and £284,720 respectively.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 6th inst., after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, amounted to £3,613.

THE "SUNBEAM" LAMP.—Messrs. Clarke, Chapman, Parsons and Co., of Gateshead-on-Tyne, inform us that the manufacture of the "Sunbeam" lamp will, on and after 27th inst., be carried on by the Sunbeam Lamp Company (Limited), Sunbeam Lamp Works, Park-road, Gateshead-on-Tyne, to whom the business has been transferred.

THE EASTERN TELEGRAPH COMPANY (LIMITED).

NOTICE IS HEREBY GIVEN, that the THIRTY-FIRST HALF-YEARLY ORDINARY GENERAL MEETING of the Eastern Telegraph Company (Limited) will be held on THURSDAY, the 19th JANUARY, 1888, at ONE o'clock in the Afternoon, at WINCHESTER HOUSE, 50, Old Broad-street, E.C., London, to receive the Directors' Report and Accounts, elect Directors and Auditors, and transact the ordinary business of the Company.

By order of the Board,
GEORGE DRAPER,
Secretary.

London, 9th January, 1888.

THE HOUSE-TO-HOUSE ELECTRIC LIGHT SUPPLY COMPANY, LIMITED.

CAPITAL £350,000

(with power to increase).

This Company is prepared to provide Residences, Offices, Clubs, Theatres, Hotels, Public Buildings, Churches, &c., with a supply of Electricity for Lighting purposes in any district where

FIFTY HOUSEHOLDERS COMBINE

to use the light.

PAST SUCCESSES.

Several of the founders of this Company have for some years past been working with success Central Stations for the generation and distribution of the Electric Current, for lighting purposes, in the towns of

BRIGHTON AND EASTBOURNE,

and, in view of the good results attained, they have determined to largely extend the field of their operations.

CENTRAL LIGHTING STATIONS.

The experience gained in these two towns proves that a Lighting Station, supplying even so small a number as 2,000 Incandescent Lamps, will yield a satisfactory return upon the capital employed in it, and

The Company will therefore be willing to lay down the necessary plant for a Central Station in any district from which applications are received from 50 householders, using a combined total of not less than 2,000 lights.

BOUND TO NO PARTICULAR SYSTEM,

the Company will start by using the system which has been perfected at Brighton and Eastbourne, but will hold themselves free to make use, from time to time, of the best methods known to carry out the production and distribution of electricity for lighting purposes.

The consumers will consequently have the advantage of the improvements that may be from time to time invented.

UNDER PERFECT CONTROL.

No machinery will be erected on the consumer's premises.

In order to obtain the electric light in the houses placed in connection with the Company's Central Stations, the occupier's servant will simply have to turn on a main switch or tap, just as the tap of a gas meter is now turned on, and the wires in the house will become instantly charged with electricity of low pressure *perfectly free from danger*, and the Incandescent lamps can then be turned on and off one by one as required.

METERS.

While the lamps are in use the quantity of the current consumed will be registered by a simple but perfectly efficient meter, PLACED LIKE A GAS METER ON THE PREMISES OF THE CONSUMER.

METHOD OF CHARGE.

Once a quarter the quantity of electricity registered by the meter will be ascertained, and the householder charged for the exact quantity consumed. If the lamps have been temporarily out of use no charge will be made, as then there will have been no consumption of current, and the leakage which so frequently happens when gas is out of use, is impossible in the case of the Electric Light.

COST OF THE LIGHT.

The quantity of current used in any particular house having been ascertained by meter, a charge will be made, as at Brighton and Eastbourne, of 1/- per Board of Trade Standard Unit (1,000 *watt-hours*), which is equivalent to a charge of about 6/- per 1,000 feet for gas.

In making this comparison it must be borne in mind that the use of the Electric Current can be greatly economised by the facility with which the lights can be turned out in unoccupied rooms.

There must also be set against the excess in cost the multitudinous advantages in the form of

PURITY,
CLEANLINESS,
COOLNESS,
CONVENIENCE,
STEADINESS,
BEAUTY,
SAFETY.

FORMATION OF CENTRES.

Those who are desirous of obtaining the Electric Light on the above terms should communicate immediately with the Company, so that steps may be promptly taken for laying down the necessary District Central Station.

Further particulars can be obtained on application to

HENRY ST. JOHN WINKWORTH,
Secretary,

HOUSE-TO-HOUSE ELECTRIC LIGHT SUPPLY COMPANY, LIMITED,
117, BISHOPSGATE STREET WITHIN, LONDON.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 505.—Vol. XX. FRIDAY, JANUARY 20, 1888. Price 4d.

NOTES.

We print elsewhere a most interesting paper, lately read by Mr. Willard E. Case, before the American Institute of Electrical Engineers, on "Electric Energy from Carbon without Heat." We have taken the liberty, however, of altering the title to "Carbon as a Positive Element." Amongst other suggestive experiments, Mr. Case finds that when carbon is attacked by perchloric acid in the presence of platinum the E.M.F. obtained with different varieties of carbon ranged from 0·3 to 1·25volt, the higher values being due, as the author thinks, to the presence of oxygen condensed in the pores of the carbon. Mr. Case thinks that there is a promising field for experiment in this direction, and certainly it is an encouraging fact that the reaction yields an E.M.F. as high as 1¼volt. Perchloric acid is, however, a decidedly uncomfortable reagent to handle. The *pure* acid will set fire to paper, and causes an explosion when dropped on powdered carbon.

Twice in the course of his new book, "The English in the West Indies," does Mr. Froude complain of the untrustworthiness of the news transmitted by telegraph through the United States to the West India Islands. We have heard on the highest authority precisely similar complaints from Canada. Indeed, there can be no manner of doubt that political intelligence relating to England passing through the States on its way to British possessions is often—nay, almost invariably—edited so as to create alarm, panic, or indignation in the English Colonies. Mr. Froude is of course mistaken in ascribing this manipulation of the text to the New York Irish telegraph operators, whose messages he conjectures are "the creation of their wishes." Irish telegraphists are the best operators in the world, and we do not suppose that their professional fidelity is affected by their residence in New York. The real offenders probably are the news agencies. But whoever they may be, it is high time their command of the telegraph wires for purposes distinctly and deliberately hostile to this country should cease.

Mr. Higgins' letter on the use of platinum wire in firedamp indicators (in our last issue) is obviously of great practical importance, and should receive careful attention from all interested in the question. It is also a very curious contribution to our knowledge of the "catalytic" powers which platinum pre-eminently possesses. Mr. Higgins finds that after having been frequently heated in the gas platinum acquires the property of igniting the gases when not itself heated by the battery current, and of becoming incandescent and exploding the mixture when gas is present in explosive proportion. It would therefore appear necessary to discard platinum altogether for the purpose in view.

Our correspondent who, in another column, ventures to impeach the theoretical soundness of Mr. Stanley's views on "The Phenomena of Retardation in the Induction Coil," prefers an indictment which we feel bound to endorse; in fact, when the paper in question first came into our hands some weeks ago, we felt that on behalf of those of our readers who are commencing the study of a confessedly difficult subject we should have deserved little thanks for its publication. Mr. Stanley has achieved a splendid success in the practical application of alternating currents, and we most ungrudgingly recognise his claims to honourable distinction as a practical electrician. But for all this, he has not proved himself to be a competent expositor of the theory of alternating currents. His present paper, moreover, is not the only evidence on which we base this opinion. But, confining ourselves to this paper, we may note the following heresies: (1) That the self-induction of a coreless solenoid produces no retardation of phase. (2) That the retardation in a secondary circuit is necessarily equal to that of the primary (this is not asserted in so many words, but is assumed in the calculations). (3) That $C^2 R$ represents the loss of energy in the armature coils of an alternating-current machine. All which (and more) we "steadfastly deny."

Mr. Stanley describes an experiment due to Mr. Shallenberger which is of singular interest, but (without disputing its accuracy) we confess that at present it wholly baffles our comprehension. Mr. Shallenberger connects four 50-volt lamps in series across a circuit having a difference of potential of 200 volts. Each lamp is shunted by a coil having an iron core which is saturated when the potential at its terminals is equal to 100 volts. If one lamp be turned off, leaving its shunt coil still in circuit, a voltmeter measures 50 volts as before across the terminals of the three lamps still alight, while across the remaining shunt it now reads 100 volts, giving a total difference of potential, as thus measured, of 250 volts. But the series of three shunted lamps and one coil measured all together reads only 200 volts as before. These are the facts derived from Mr. Stanley's paper, but we can offer no ex-

Digitized by Google

planation. Next week we hope to describe a practical device of a novel and highly ingenious description in the distribution of alternating currents which has been introduced by Mr. STANLEY with perfect success.

IN a lecture recently delivered before the Franklin Institute Prof. HAUPT has been astonishing the American world by his calculations on the savings to be effected by rapid transit. He calls the results "intensely practical," and insists that the prosperity of a community is fostered by recognising the facts he discloses. We do not feel quite so sure about it ourselves; but our readers can judge. By doubling the velocity of the street cars in Philadelphia half an hour might be saved for each passenger, and a saving of 23,148 years would annually be effected on the aggregate passengers using the cars. At first we were inclined to suggest that the passenger would save his time altogether by not taking the ride. But the curious professor assumes that everybody must ride or walk, and he evidently is dead against walking—a method of locomotion which involves a loss in New York computed at 8,333,333 horse-power energy per annum. To effect a large economy in this item he proposes to create fresh thoroughfares, cutting through the existing blocks diagonally. It strikes us that this would drive many people out of their homes and compel them to live farther away from their occupations, a result doubtless profitable to the street cars, but not to the inhabitants. After all, perhaps, both as regards the time saved in riding, and the energy saved in not walking, everything depends on what you do with the savings.

IT is difficult to attach much credence to the story which has been making the round of the press as to the cases of "sunstroke" said to have been caused by the electric furnace at the Creuzot works. Electric furnaces are scarcely novelties, and had such an effect been possible we should have expected to hear of it before this.

IF the thermo-magnetic generator should in the future prove to be an economical source of electric energy, it will be a matter of some regret that our English electricians have not taken a more prominent part in its development. But we shall at least have the satisfaction of knowing that the earliest investigations—so far as our present knowledge goes—of the conversion of heat into electrical energy by means of the thermo-magnetic properties of iron were carried out in this country. In another column will be found a reprint of a paper on this subject communicated to the Royal Society by Dr. G. GORE in 1869. It will be seen that the experiments are of a very simple and very beautiful character, and so suggestive that it appears strange that they should have remained on record all these years without bearing fruit. It is also interesting to know that eleven years earlier, in 1858, Dr. GORE had made some experiments in the same direction, though without results. In these earlier attempts a vertical tubular magnet was surrounded with a coil of insulated wire connected with a distant galvanometer. Into the axial cavity of the magnet red-hot sand was suddenly poured. However, as no result was attained the experiment remained unpublished.

IF any justification were needed for our remarks last week on the subject of Electricity and the Medical Profession, surely it is abundantly supplied by an article in the *Lancet* of Saturday last "On the Electrical Basis of Vital Motion." The author is a personage of no less distinction than Dr. C. B. RADCLIFFE, F.R.C.P. (Consulting Physician to the Westminster Hospital, Physician to the National Hospital for the Paralysed and Epileptic, &c.). Dr. RADCLIFFE expresses an opinion that the electrical phenomena displayed by nerves and muscles are the results "not of any electrical action confined to the muscular system, *but of an electrical action extending to the whole solar system and not limited to it.*" (!)

BEFORE proceeding to quote further from this paper, it will be well to remind those of our readers who may not be familiar with the *facts* of electro-physiology, that some forty years ago Du Bois Reymond discovered that if a living muscle be cut transversely across, a difference of electric potential may be shown to exist between the *end faces* and the sides of the muscle; but this phenomenon ceases with death. It is to explain these facts—admittedly difficult to understand—that Dr. RADCLIFFE invokes the electrical energies of "the whole solar system." The paper winds up with a discussion of the causes of "epilitiform convulsion," on which we do not presume to offer an opinion; but as for the passage which we quote at length below, we do not hesitate to pronounce it hopelessly fallacious and utterly unscientific in form. In fact, the method of argument (?) is more closely akin to that of the Schoolmen of the Middle Ages than to the recognised inductive methods of modern science. We shall not, however, try the patience of our readers by any detailed criticism, and we trust it will be understood that we write this not at all in the spirit of captiousness, but in the hope that the members of a learned profession which to-day, as always, numbers in its ranks some of the ablest workers and most careful thinkers of the age, will see to it that the exploration of the borderland of electricity and physiology shall be conducted in a manner worthy both of their profession and of ours.

AFTER the sentence already quoted the writer in the *Lancet* proceeds as follows :—

"At spring-tide and at neap-tide, when the action of the sun and moon are most differentiated, there are variations in terrestrial heat which show very plainly that the moon as well as the sun is directly concerned in producing these variations. There are variations in terrestrial magnetism at the same time which as clearly tell the same story. And there are cotemporaneous variations of the same sort in atmospheric potential, only as yet not so clearly made out as the variations in heat and magnetism. And the deficiency in the evidence here is supplemented by the presence of the belt of terrestrial magnetism, and by the requirements of the doctrine of the correlation of the physical forces : by the presence of the belt, because the very existence of magnetism is inconceivable apart from electricity ; by the requirements of the doctrine, because these oblige me to regard heat and light, and electricity and magnetism, and the other forms of physical forces, as mere modes of one and the same force. Indeed, there is, as I have attempted to show elsewhere, good reason to believe that the earth is continually acted upon by electricity which has its source in an electrical interaction which is always going on between the sun and moon on one hand and the earth on the other, and that this elec-

tricity is manifested in the form of currents across the earth from the sun and moon, the case being really one in which it is easy to believe that the dielectric sheaths of the fibres in nerve and muscle may be charged, as Leyden jars are charged by these currents, and that this charge will be instantly renewed after discharge. Nor can it be said that these currents are not powerful enough to do all this, for, as atmospheric potential is equal to several hundred volts at a short distance above the earth, and to still more than this as this distance increases, and as the directive power of the terrestrial magnetism is not altogether annihilated by the most powerful artificial magnetism, it is only fair to conclude that the solar and lunar currents are powerful enough to do all the work they have to do in charging the sheaths of the fibres in nerve and muscle, as Leyden jars are charged, and in instantly renewing this charge after discharge."

THE singular unanimity of opinion, both in this country and America, which found emphatic expression at the Eastern Telegraph Company's meeting yesterday, with regard to the honour recently conferred upon the Chairman of that Company, is perhaps the more justifiable from the fact that K.C.M.G. is usually a Colonial distinction, and seems to point in this instance to Sir John Pender's services in connection with the Colonies. What the British cable interests would seem to desire, and very naturally, is a recognition in some more appropriate form of Sir John's immense services to the country and the world in founding and developing British Submarine Telegraphy.

Copper.—After several fluctuations during the week copper fell considerably, Chili bars being yesterday quoted as low as £75. 2s. 6d.

Japan.—The electric light is becoming increasingly popular in Japan. A number of plants have recently been fitted up at Sakamotocho and Kyabacho.

Postponement of Sale.—The sale at Tufnell Park Mills, advertised to take place on the 25th inst., has been postponed till further notice (*see* our advertisement columns).

Postal Telegraph Appointments.—Mr. J. Murray, the clerk in charge of the telegraph office at Wick, has been appointed postmaster of that town, and Mr. M. Tuohy, telegraphist at Mallow, has been appointed postmaster of Bandon.

The Electro Harmonic Society.—The next smoking concert of this society will be held at St. James's Hall on Friday evening next, Jan. 27. We would direct the attention of our readers to the programme, which will be found in another column.

The New York Electric Club.—The new premises of this club will be formally opened on Tuesday evening, January 31st, when Prof. H. A. Rowland will deliver an address. We offer our hearty congratulations to the club on this auspicious occasion.

Tunbridge Wells.—At a meeting of the Tunbridge Wells Tradesmen's Association on Tuesday it was stated that a company was being formed to supply the electric light in the town. The tradesmen unanimously adopted a resolution favouring the introduction of the light.

Turin.—MM. Bellani, of Turin, have secured the rights of the Thomson-Houston system for Italy. This firm has maintained 30 arcs of 2,000 candle-power in one of the main streets of Turin during the last six months. The Thomson-Houston system is also represented in Italy, at Milan, and at Palermo.

Proposed Telephone Line from Brussels to Cologne.—Notwithstanding the fact that the German Government recently interdicted the use of existing telephone lines crossing the French and Swiss frontiers, they are, it is stated, inclined to sanction a project for laying a line between Brussels and Cologne, and it is believed that the work will shortly be undertaken.

The Electric Motor in Building Operations.—At Topeka, Kansas, several Sprague motors are in use for raising bricks and mortar, &c., upon the scaffolding of a large building in course of erection. Current is obtained from a neighbouring central station. The method proves to be much more economical than that of the employment of a steam crane, because the work is essentially of an intermittent description.

Leamington.—We regret to record that some trouble has arisen at the Leamington Central Station owing to an intermittent short circuit which has established itself somewhere in the mains, and had up to a few days since defied detection. A number of lamps had in consequence been cut out of circuit. The matter came before the Town Council, when a letter was read from Mr. Arthur Chamberlain expressing a hope that a permanent cure would be effected in a few days.

Ireland.—Telegraphs for Coastguards.—The staff of Engineers employed by the Irish Board of Works have received instructions to furnish as speedily as possible estimates of the cost of establishing telegraphic communication between the several Coastguard stations around the coast of Ireland. This step is being taken with a view to increasing the efficiency of the existing arrangements for detecting the landing of contraband articles, as well as with a view to strengthening the coast defences.—*Standard.*

The Observation of Earth Currents.—In accordance with an engagement entered into by the Spanish Government at the International Congress of Electricians held at Paris in 1881, two telegraph wires are about to be laid in Spain for the express purpose of making observations on earth currents and on atmospheric electricity. One of the lines will run due north and south, and the other due east and west, each line being eight kilometres in length. They will cross each other at the astronomical observatory of San Fernando.

Mill Lighting.—As an instance of the rapidity with which the electric light may sometimes be installed, Messrs. W. R. Dell and Son, of 26, Mark-lane, London, E.C., inform the *Miller* that, in the case of Mr. Cole's mill at Lipton, the light was working within a fortnight from the date on which they received the order. A very brisk business with electric lighting is reported by Mr. Wilson Hartnell, of Leeds, who states that he has just completed a mill at Penzance belonging to Messrs. Bageley and Sons. He has in hand also a 250 installation for Messrs. Reynolds, of Haslegrave, Wakefield, who have had one of Mr. Wilson Hartnell's installations at work for the last four or five years.

The Hanover-square Electrical School.—A handsomely got-up pamphlet describing the objects of this well-known establishment has just been issued by its managers. The school, which began 20 years ago by teaching ordinary telegraphy, soon developed into an institution for training superior operators, mainly for submarine cable work, but of late years has extended its aims to the teaching of electrical engineering. In all three departments its success has been conspicuous; and in combining the practical with the theoretical side of its tuition, "The School of Electrical Engineering and Submarine Telegraphy," in Princes-street, Hanover-square, occupies a quite exceptional position among the higher educational establishments of the country.

"Anti-Pulsator" for Gas Engines.—Messrs. George Bray and Co., the well-known gas engineers of Leeds, are introducing

Digitized by Google

a simple apparatus, which they call an "anti-pulsator," intended to obviate the irregularities of working of gas engines, when due to variations in the pressure at which the gas enters the compression cylinder. There is no doubt that such variations of pressure are often the sole cause of the complaints arising from the unsteadiness of gas engines when employed for the electric light. Messrs. Bray state that with their apparatus it is possible to supply gas burners from the same meter as that used for the engine without causing any unsteadiness in the light. The "anti-pulsator" appears to be well worth the attention of electric light engineers.

Electric Locomotives on the Underground Railway.—The *Globe* now announces that the arrangements, which we foreshadowed some weeks ago, have been completed between the Metropolitan Railway Company and the Electric Traction Company for experimental running upon a section of the railway outside the circle of a locomotive of the same power as the present steam locomotive. The Electric Traction Company stipulate that should the experiment prove an advantageous and economical method of working, they are to have the option of entering into an agreement for working the railway by electricity for a term of five years at a rate per train mile to be agreed, such rate not to be in excess of the cost of working by means of steam locomotives.

The Mexican Telegraph Company.—The New York correspondent of the *Mexican Financier* reports the substance of an interview with Mr. Scrymsek, the President of the Mexican Telegraph Company, in which reference is made to the steady improvement of business over that company's lines. This is attributed to the increased commercial development of the Republic; to the improved condition of the Government lines, to which we referred some time ago; and to the greater use of telegraphy by merchants in remote parts of the Republic. Attention is also drawn to the accuracy of the service over the lines of the Mexican Telegraph Company. It is stated that in a total of 170,000 words transmitted in September last (presumably to New York) only ten errors were made, while in October there were again but ten errors out of a total of 180,000 words transmitted.

The Burmese Telegraphs.—The *Indian Engineer* says:—"We are glad to be able to state that Mandalay will soon be in direct telegraphic communication with Calcutta. The work of laying down the different sections of the line has already been begun. The line between Mandalay and Alon has been complete; that from Alon to Myingyan is now being laid under the supervision of Mr. G. O'Hara, sub-assistant superintendent; the second line from Myingyan to Kendat will be laid by Mr. Whitby Smith, assistant superintendent; and a third section from Kendat to Thaumboo, a station not far from Manipur, in Assam, whence the whole extension to Calcutta will be completed, the whole of the line being constructed in five or six months. The parties who are to go out on the work of construction will be escorted by armed troops consisting of 25 or 30 men or more, the numbers depending on the state of the country through which a party may have to pass, these regions being at present infested by dacoits."

Bath.—The second meeting of the Electric Lighting Committee of the Bath Town Council took place on Thursday at the Guildhall. The chairman said he had much pleasure in laying before the committee the information asked for at the last meeting. With a view to obtaining it from the most reliable and independent sources, he had written to the scientific and technical papers devoted to electrical engineering, asking in what towns in the United Kingdom the electric light had been adopted, and in what places it had proved successful, or been abandoned. After a long discussion it was pointed out that all agreed that the most successful installation was the one at Taunton, and the town clerk was requested to put himself in communication with the town clerk of that town, and ascertain particulars respecting the system in use there, and report the result of his inquiries at the next meeting.

The West Coast of Africa Telegraph System.—A correspondent writes from Accra:—"In the course of his speech to a large assemblage, composed of native kings, chiefs, merchants, and others at Accra, his Excellency (Sir W. Brandford Griffith, K.C.M.G., Governor of the Gold Coast Colony) referred in eulogistic terms to the advent of the cables of the West African and African Direct Telegraph Companies. He said we had much to be thankful for to these companies in establishing their lines of communication to this colony, for there can be no doubt that they have considerably helped to bring civilisation and promote competition in trade, which can only tend to improve its condition; and these companies were conducted by gentlemen of intelligence and culture, combined with social qualities of a high order, and they had, moreover, erected buildings of architectural designs worthy of themselves, and which he hoped would be followed as an excellent example."

An Electric Sentinel.—Mr. Daniel Drawbaugh, whose name is well-known in connection with telephone suits in the United States courts, has devised an apparatus which he proposes to employ in connection with military operations as an automatic sentinel. The apparatus is to be buried in the earth at the outposts, and connected by an insulated wire with head-quarters. According to the published descriptions—which are not of a very lucid character—the recording instrument appears to consist of a delicate relay, closing a second circuit through a mercury contact, and so actuating a registering mechanism. The relay is said to be operated by the disturbance of the current produced by a microphone contact which constitutes the transmitting apparatus. It is difficult to suppose that there is anything practical in this suggestion. Even if technical difficulties have been overcome, we do not see how the microphone is to distinguish friends from foes, or rabbits from human beings; and a sentinel who is unable to do this is evidently of very little use.

York.—Messrs. Rowntree, Hills and Co., of York, have recently lit their premises by electric light. The installation, which has been carried out by Messrs. J. H. Holmes and Co., Newcastle-on-Tyne, consists of one of their No. 8 "Castle" dynamos (compound wound), giving 70 amperes, 60 volts, at a speed of 1,000 revolutions, driven by a 6 horse-power "Stockport" gas engine. The shops are lighted by nine of J. H. Holmes "Castle" arc lamps, which received a silver medal—the highest award—at the Newcastle Exhibition, and five small ones, giving 400 candle-powder with a current of 5 amperes. The offices at the back of the premises are lighted with 60-volt Swan lamps. The arc lamps employed in this installation are of Messrs. Holmes and Co.'s new and improved type, including their recently patented arrangements for ensuring a definite feed, and thus regulating the lamps with great certainty. The creamery is elaborately panelled with decorated tiles, and the small arcs in this department give a charming effect.

The Lighting of the City.—The *City Press*, commenting on this subject, says:—"There can be but little doubt that we have been deprived of the proper use of this most brilliant discovery, for many years, by the blundering legislation proposed, and unfortunately carried into effect, by Mr. Chamber-

lain when one of Her Majesty's Ministers. He was so fearful of establishing a monopoly in the supply of electricity, similar to that existing in regard to gas, that he hedged round any attempt at a contract for public lighting with such stringent, not to say absurd, conditions that our streets have remained in the same condition of semi darkness as before, and now that, after so lengthened a consideration, a contract has at length been prepared that promises to give us the same beautiful lighting that we see with envious eyes elsewhere, we do most sincerely hope that the Streets Committee will be able to obtain such a modification of it in the way suggested by the dissentients as will remove what seems to be their one objection to its adoption."

Electro-Plating with the Dynamo.—A paper on this subject was lately read before the Electro-Technical Society of Vienna by Wilhelm Penkert. After an historical sketch of the subject from the first attempt in 1875 at the Austrian State printing office to the present day, the author gives some interesting hints from modern practice. For smaller baths earthenware, free from acid, is found the best; for larger sizes wooden baths lined with lead, which in its turn is covered with large glass plates, may be used, as the resin on the lead is found to have a bad effect on the deposit. The experiments carried out by Baron Hübl at the Military Geographical Institute were mentioned as showing that with a current density of 1·3 ampere per square decimeter (= ·084 ampere per square inch) in a bath of 20 per cent. solution of copper sulphate, with 3 per cent. sulphuric acid added, a deposit is obtained which is tougher than rolled and hammered copper, and almost as elastic, strong, and hard. Baron Hübl had also shown that the anode used is not composed of copper oxide, as formerly supposed, but of pure metallic copper.

A New Petroleum Engine.—A new description of petroleum engine, the invention of Mr. Shipman, an American, has been recently exhibited in this country. It is designed to burn any kind of liquid fuel, and to be as self-regulating in the use of this form of combustible as the gas-engine with coal gas. It is stated that this end is so far achieved that the engine works for hours with varying loads and without supervision; the fire and the water supply always adapting themselves to the work to be done. The oil runs from a tank into a pipe situated a few inches below the furnace. From this pipe it is drawn up by two atomizers fed with steam from the boiler; and in this way the furnace is fired. The steam supply to the atomizers passes under a diaphragm, to which a valve is attached; and as the diaphragm is loaded, so it cuts off or opens the passage for the flow of steam, according as the steam pressure rises or falls. Thus the steam can never rise beyond the determined pressure; because as soon as this limit is attained, the fire is extinguished. A pilot lamp is provided for lighting the fire again when the pressure falls sufficiently to open the valve. Practically, of course, the fire need scarcely be extinguished at all, for the consumption of oil can be adjusted to the average amount of evaporation required by the ordinary working of the engine. The water supply is also controlled by a float connected by a lever with a cock on the suction pipe of the pump. The boiler is of peculiar construction, being rectangular, with a cluster of blind tubes projecting from one side among which the heat circulates. The consumption of fuel is stated to be about three pints per indicated horse-power per hour.

Spanish Telegraph Statistics.—The general Board of Posts and Telegraphs in Spain have just issued the telegraph statistics for the second half of 1886. The publication of such statistics after the lapse of twelve months may seem late, but a leading Madrid paper says that the delays in compiling official statistics in Spain are so great that it is a matter of congratulation that they should have appeared so soon. It appears from the statistics that at the 31st December last the length of overhead telegraph wires in Spain was 18,419 kilometres, underground wires 144 kilometres, and submarine wires 236 kilometres. The number of despatches during the six months, distinguishing internal and foreign, private, public, and service messages, was as follows:—Interior—Official, 186,453; service, 53,508; private, 1,176,507. Foreign—Official, 6,100 messages despatched and 4,383 received; private, 180,952 sent and 202,826 received; and transit messages 50,593. The revenue amounted to £134,270. The total number of messages for the twelve months ended 31st December last was 3,549,860, of which 801,656 were international, and 2,748,204 were internal. Of the latter 372,407 were official, 108,323 were service telegrams, and the rest—2,267,574—private. The year's receipts were £237,515, and the expenditure £308,440, in the proportion of £195,025 for *personnel*, and £114,415 for lines, stations, &c. There was, therefore, a deficit for the State of some £70,925. The Spanish telegraph service certainly seems to be going from bad to worse as a source of revenue. The *Dia* of Madrid, commenting upon the result, says that four years ago, viz., in 1882, the length of lines was 16,744 kilometres, and the total cost was £193,875. Since then the addition to the wires has only been 1,675 kilometres, but the expenditure has increased by some £114,565, while the revenue has increased £40,790. It would therefore appear that the Spanish telegraph service, which was profitable in 1882, has now become a serious loss to the State.

A New Departure in Brazing and Welding.—Mr. Fletcher, the well-known gas engineer, writes us as follows:—"The cheapening of oxygen by Brin's process of manufacture has put into the hands of metal workers a new power. I have recently made a few experiments with the compressed oxygen and coal gas, and found that with a ½in. gas supply a joint could be brazed in a 2in. wrought-iron pipe in about one minute, the heat being very short, the redness not extending over 1in. on each side of the joint. The appearance of the surface after brazing led me to experiment further with welding, a process which is not possible with ordinary coal gas and air, owing to the formation of magnetic oxide on the surfaces. Contrary to my expectation, a good weld was obtained on an iron wire ⅛in. diameter with a very small blowpipe, having an air jet about $\frac{1}{32}$in. diameter. This matter requires to be taken up and tried on a large scale for such work as welding boiler plates, which, it appears to me, can be done perfectly with far less trouble than would be required to braze an ordinary joint. The great advantage of this would be that the boilers would require no handling, but could be welded with an ordinary large blowpipe in position, and with about one-tenth the labour at present necessary. The cost of the oxygen is trifling, and it is evident from the results obtained in brazing that the consumption of gas would be considerably less than one-fourth that necessary with an air blast, irrespective of the fact that welding is possible with an oxygen blast, whereas it is not possible if air is used. The surface of iron heated to welding heat by this means comes out singularly clean and free from scale, and a small bottle of compressed oxygen with a blowpipe and a moderate gas supply would make the repairs of machinery, boilers, brewing coppers, and other unwieldy apparatus a very simple matter. The trouble and difficulty of making good boiler crowns, which so frequently come down, would be very small indeed when the workman has an unlimited source of heat at command, under perfect and instant control."

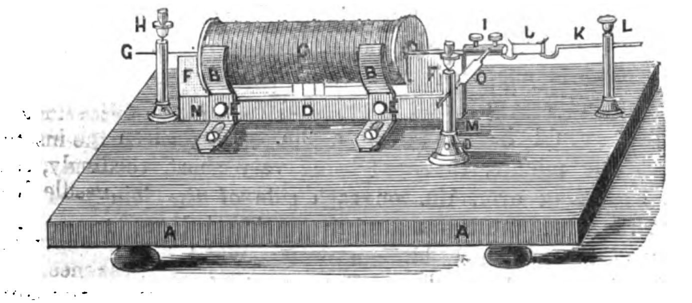
EARLY RESEARCHES IN THERMOMAGNETIC GENERATORS.

Nearly twenty years ago some experiments were brought before the Royal Society by Dr. G. Gore, F.R.S., in which the principle of the thermomagnetic generator is fully exemplified. The paper will be found in the *Proceedings Roy. Soc.*, Vol. XVII., p. 261, 1868–9, and also in the *Phil. Mag.*, Vol. XXXVIII., p. 60, 1869; under the title, "On the Development of Electric Currents by Magnetism and Heat." The subject having now entered upon a further stage of development, we reproduce here the figure illustrating the experiments, together with an extract from Dr. Gore's paper as follows.

"I have devised the following apparatus for demonstrating a relation of current electricity to magnetism and heat:—

"A A, Fig. 1, is a wooden base upon which is, supporting four brass clamps (two, B B, on each side), a coil of wire, C; the coil is 6in. long, 1½in. in external diameter, and ⅜in. internal diameter, lined with a thin glass tube; it consists of 18 layers, or about 3,000 turns, of insulated copper wire of 0·415mm. diameter (or size 26 of ordinary wire gauge); D is a permanent bar magnet held in its place by the screws E E, and having upon its poles two flat armatures of soft iron, F F, placed edgewise. Within the axis of the coil is a straight wire of soft iron, G, one end of which is held fast by the pillar screw H, and the other by the cylindrical binding screw I; the latter screw has a hook to which is attached a vulcanised india rubber band, J, which is stretched and held secure by the hooked brass rod K and the pillar screw L. The screw H is surmounted by a small mercury cup for making connections with one pole of a voltaic battery, being secured to the pillar screw M, which is also mounted by a small mercury cup, and is connected with the cylindrical binding screw I by a copper wire with a middle flattened portion, O, to impart to



it flexibility. The two ends of the fine wire coil are soldered to two small binding screws at the back; those screws are but partly shown in the sketch, and are for the purpose of connection with a suitable galvanonometer. The armatures F F are grooved on their upper edges, and the iron wire lies in these grooves in contact with them; and to prevent the electric current passing through the magnet, a small piece of paper or other thin non-conductor is inserted between the magnet and one of the armatures. The battery employed consisted of six Grove's elements (arranged in one series) with the immersed portion of platinum plates about 5in. by 3in.; it was sufficiently strong to heat an iron wire of 1·03mm. diameter and 20·5 centimetres long, to a low red heat.

"By making the contacts of the battery in unison with the movements of the galvanometer needles a swing of about 12deg. of the needles each way was obtained. The galvanometer was not a very sensitive one; it contained 192 turns of wire. . . . The maximum effect of 12deg. each way, with six Grove's cells in one series was obtained, when the wire became visibly red hot, and this occurred with an iron wire, 1·03mm. diameter (or No. 19 of ordinary wire gauge). By employing a thicker wire and a battery of greater heating power, still greater effects were obtained. The galvanometer was placed about 8ft. (in some instances 12ft) distant from the coil. A reversal of the direction of the battery current did not reverse or perceptibly affect the current induced in the coil; but by reversing the poles of the magnet the direction of the induced current was reversed. On disconnecting the battery, and thereby cooling the iron wire, a reversed direction of induced current was produced. By substituting a wire of pure nickel, 24·5 centimetres long and 2·1mm. in diameter, induced currents were obtained as with the iron, but they were more feeble. No induced current occurred by heating the iron wire if the magnet was absent; nor was any induced current obtained if the magnet was present, and wires of palladium, platinum, gold, silver, copper, brass, or german-silver were heated to redness instead of iron wire; . . . it is evident, therefore, that the axial wire must be composed of a magnetic metal. . . .

"The direction of the induced current by *heating* the iron wire was found by experiment to be the same as that which was produced by removing the magnet *from* the coil; and therefore the heat acted simply by *diminishing* the magnetism, and the results were in accordance with, and afford a further confirmation of, the general law, that wherever there is increasing or decreasing magnetism, there is a tendency to an electric current in a conductor at right angles to it."

(To be continued.)

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

(Continued from page 235.)

CHAPTER VI.—*Current Indicators (continued).*

66. As regards telephone circuits and instruments, the detector is an indispensable item of an inspector's kit, who will frequently require it to detect any fault in his instruments or examine the condition of the batteries. The more portable, while reliable, of course the better, and some of the telephone companies have in use the pocket type described. As the batteries used are generally Leclanché's and the resistances met with rather under than over 50ω, the detector would be wound to that resistance or less, according to the resistance of the induction coils and receivers and the type of battery in use.

67. For dynamo or accumulator circuits where the resistances are very small, detectors for showing the direction of the

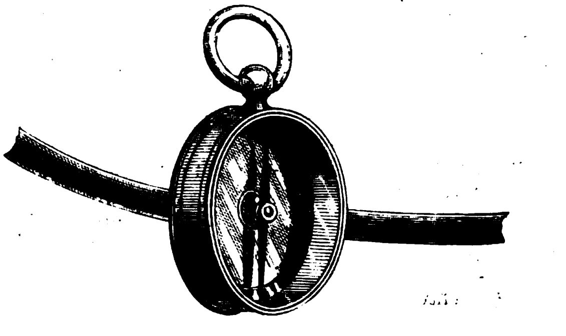


FIG. 27.

current or ascertaining whether it is constant, are in use and are wound with a few turns of thick wire to resistances from 1ω to $\frac{1}{100}$ω, or even less. In fact, with ordinary electric lighting currents, say from 10 amperes upwards, no coil is required at all as far as finding the *direction* of the current is concerned; an ordinary pocket compass placed over the main wire at any part of the circuit will show the direction of current at once. The compass-needle will try to set itself at right angles to the wire in which the current is passing. If the north pole of the needle turns to the *right* the current will be flowing *away* from the observer, and *vice versâ* (see Fig. 27). It will easily be seen whether the current is strong by the rapidity of the oscillations made by the needle when placed over the main wire; and if the current was a feeble one, causing very sluggish oscillations, as it would, under the influence of the earth's field alone, a portion of the main wire should be

Digitized by Google

selected which lies north and south, or a few inches of it may be easily bent into this direction before applying the compass test; it can then be seen quite well towards which direction the needle tends to turn from the meridian, the earth's field tending to keep it parallel to the wire, and the field produced by the current tending to move it away from a parallel position.

68. On this principle an engine-room current indicator is easily constructed with a magnetic needle freely suspended over a single broad band of copper, the ends of which are attached to terminals outside the instrument. The writer recollects seeing an indicator of this kind, with a vertically-suspended needle placed where it could be readily seen, in the engine room at one of the London exhibitions. It was in the circuit of six arc lamps, which served to illuminate the grounds from the top of a high mast, and the dynamo attendant could see by it quite well whether his lamps were burning all right or one was failing. There being no bobbins or coils the instrument is extremely simple to make, and, if required, can be calibrated in amperes by comparison with some ammeter whose constant is known. One is illustrated in Fig. 28, the copper or brass band behind the needle being shaded, and the

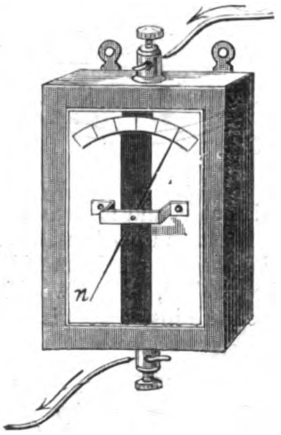

Fig. 28.

needle itself having its north end downwards. The direction of deflection for a given current is then that shown.

69. A question that will naturally suggest itself from the last few observations will be: Does not the current in the leading wires attached to a *measuring* instrument affect its readings? As a matter of fact it does with a weak controlling field, and the precaution must be taken of twisting the two leading wires as they approach the instrument, so neutralising the extraneous field they produce. If, however, the instrument has a powerful magnetic controlling field the effect is practically *nil*, and there is no necessity for the above precaution. In all cases, before readings are taken, it can be noticed whether, when the current is on, the leading wires affect the needle by shifting their position relatively to the latter and observing whether any alteration occurs in the number of degrees deflection.

70. Large telegraph stations and telephone exchanges have in use a large number of cells, in some cases of different types for local circuits or line work, and the battery man has to keep a spare set of cells ready to put on to a circuit in case any should "run down." In cable stations there are in addition sets of very low-resistance "tray" cells for magnetising the electro-magnets of the recorder instrument. An indicator with coils of different resistance for testing the condition of cells of different types is then a requisition. A form of indicator fitted in this way (by Messrs. Elliott Brothers) is shown in Fig. 29, the coils being respectively of 2, 10, and 1,000 ohms. Batteries or circuits to be tested are connected to the instrument at A and B, and the plug P is inserted in the hole opposite the number showing the resistance of the coil required. This arrangement of brass bars and movable plug is technically called a "commutator;" a plan of this portion is shown in Fig. 30 with the connections to the coils. The current can be made to pass from one terminal to the other through any of the coils by inserting the plug at the bar marked with its resistance. The high-resistance coil is wound with many turns of fine wire, and the two-ohm coil with a few turns of thick wire.

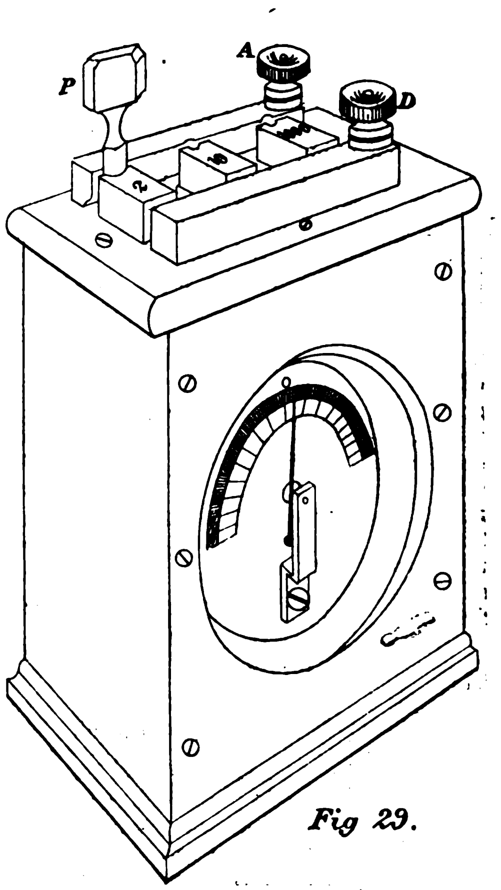

Fig 29.

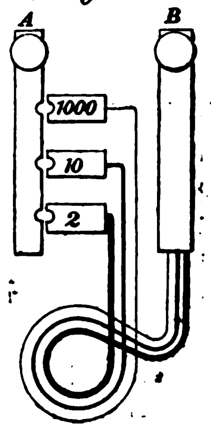
71. Should the needle of a vertical detector lose its strength of magnetism to any extent the deflection given by the instrument with a given current will be weakened accordingly, but as the north pole is the weighted or lower end the needle lies in a favourable position as regards the earth's field in this latitude for maintaining its polarity, and it will probably be years before its magnetism becomes sensibly weakened. If strong currents, however, are put through the instrument,

Fig 30.



especially if the circuit is disconnected and connected several times in succession, the magnetism of the needle may become affected. This is the more noticeable in telegraph needle signalling instruments, which are connected to a long length of overhead wire. Atmospheric electrical discharges

Digitized by Google

take place at times through the wire, and if the instrument protectors do not act, the needle may become partially demagnetised, or even have its magnetism reversed. Devices for preventing this will be considered later on in this series when telegraph apparatus is examined. The needle signalling instrument, however, is mentioned at this point because its internal construction is exactly the same as the vertical indicators which have just been considered.

72. When the needle of an indicator is pivoted so as lie horizontally, any weakening of its magnetism has very little effect on the sensibility of the instrument. The reason for this is that the controlling force, or force tending to maintain the needle at zero, is that of the earth's field, the actual amount of that force acting at each end of the needle being the product of the earth's field and the strength of one of the needle poles. On the other hand, the force exerted at each end of the needle by the current in the coils, tending to move it away from zero, is equal to the product of the field of the coil and the strength of one pole of the needle. Since both the moving force and the controlling force depend equally on the magnetic strength of the needle, the ratio between them is simply the ratio of the respective fields of the coil and the earth, and the needle will therefore take up a position depending on the relation between the two fields irrespective of the actual strength of the needle poles; unless, indeed, they are entirely demagnetised, in which case there would be no moving or controlling force at all, except, probably, irregular forces caused by magnetic induction.

The friction on the pivot, however, which is a negligible quantity when the needle is strongly magnetised, becomes an appreciable obstacle to its movement when its magnetism is weakened, for while the *relation* between the moving and controlling forces depends simply on the two fields, and therefore is unaltered by weakening the magnet, it will be seen by what was said above that the *actual amount* of these forces is proportionately reduced as the magnet becomes weaker, and that therefore the needle is not drawn towards or held in its deflected position with the same force and with the same facility of overcoming friction as when it is strongly magnetised.

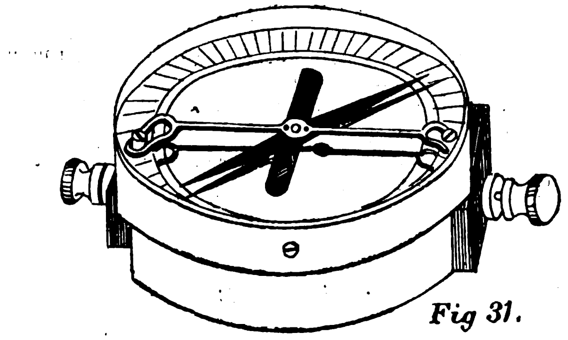


Fig 31.

The horizontal pivoting of needles, however, admits of very sensitive mounting of the needle spindle. Illustrated in Figs. 31 and 32 are two very sensitive indicators of this class by Messrs. Elliott Bros. In Fig. 31 the spindle joining the two parallel magnetic needles, whose opposite poles point the same way, is pivoted in jewel centres and constitutes an indicator that may be very well used with proper calibration for a number of useful tests requiring accuracy. The dial is about 3½in. diameter, and the coil is wound to $1,000\omega$ resistance.

There is only one magnetic needle in the instrument represented in Fig. 32, the pointer, which indicates the deflection, and is fixed at right angles to the needle, being non-magnetic. When the instrument is used the coils must be turned round until they lie in the same plane as the needle *n s* (*see* Fig. 33). Now, as it would be impossible to read small deflections with the coil impeding the view, a non-magnetic pointer, *p*, is attached at right angles to the needle which points to zero when the instrument is ready for use, and whose angular deflections are of course the same as those of the needle. The screw seen at *s* in Fig. 32 is fixed to the glass lid of the needle box, serving to remove it when required. The metal arm A serves to connect together the two terminals, or, as it is termed, "short-circuit" the instrument. This might be required if the instrument was connected to a circuit where a current was continually flowing, the short-circuit being removed every time a reading had to be taken, and then replaced, so that the current would only pass through the coils when a reading was required. The coil of this indicator is

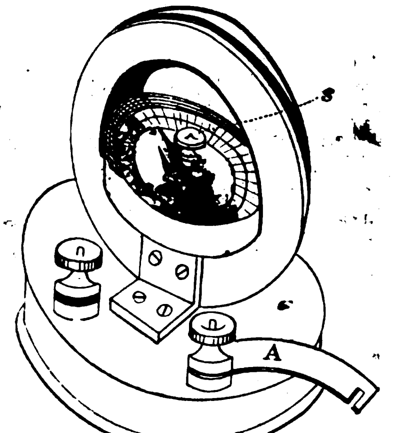

Fig 32.

about 4in. outside diameter, and is wound to a low resistance. When the indicator is set and used as above—that is, with the plane of the coil in the magnetic meridian—a deflection of 90deg. can never be reached, as this would require an *infinite* current, and, moreover, the instrument is so unsensitive to slight

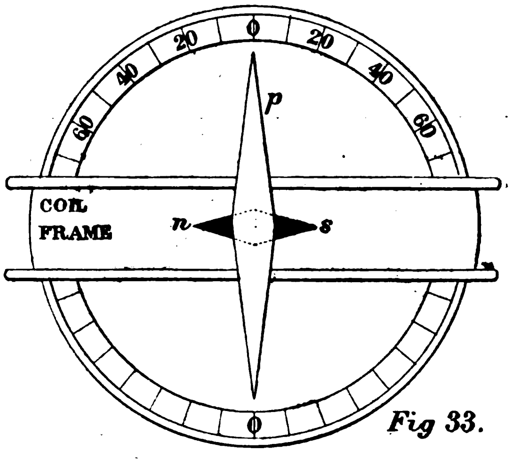

Fig 33.

changes of current when the deflection is above 75deg. that deflections are usually kept below this, if possible, when a test is taken involving reading two deflections representing two strengths of current nearly the same; in fact, the readings are most sensitive when the needle is at an angle of 45°. For testing, where slight changes in current have to be read, the deflection should therefore be first brought to this angle either by altering the resistance in the circuit or by shunting the instrument.

(*To be continued.*)

THE THERMO-MAGNETIC PROPERTIES OF IRON AND NICKEL.

In our last issue we mentioned that we hoped shortly to publish the thermo-magnetic curve of nickel, a subject which M. Menges is at present engaged in investigating. We are, however, indebted to a paper by M. Ledeboer in *La Lumière Elec-*

Digitized by Google

trique of January 14th for a knowledge of the fact that such curves have already been published by M. Berson in the *Annales de Physique et de Chimie*, Vol. VII., p. 433, 1886, and we reproduce in Fig. 1 the curves so obtained. It will be seen that the change takes place very abruptly, and that a variation of temperature between 220deg. C. and 320deg. C. is capable of producing the maximum possible effects. The increase of temporary magnetisation with the simultaneous decrease of permanent magnetisation during the first portion of the curve is very singular.

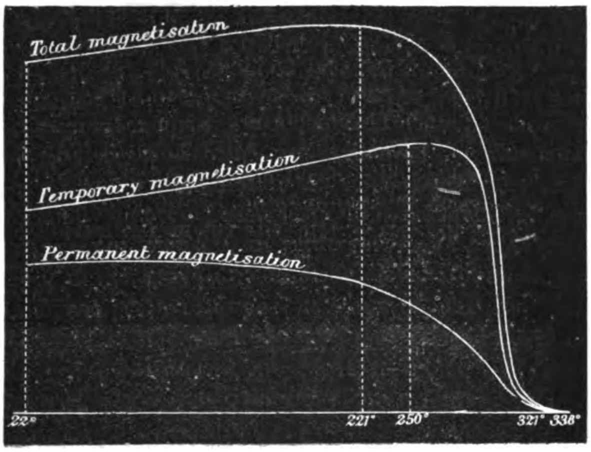

Fig. 1.—Thermo-magnetic Curves of Nickel.

The paper by M. Ledeboer above referred to contains also the results of some recent investigations of the author on the thermo-magnetic properties of iron. The iron to be experimented upon was wrapped with a coil of platinum wire, wound differentially so as to produce no magnetic field, and insulated

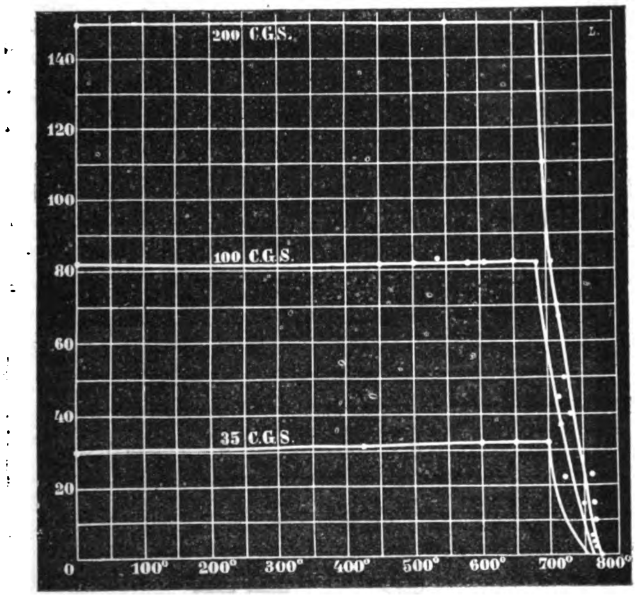

Fig. 2.—Thermo-magnetic Curves of Soft Iron.

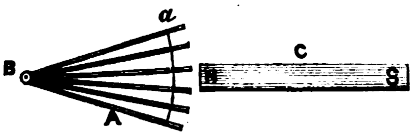
from the iron by thin leaves of mica. The bar so prepared was surrounded by a copper cylinder, and this was placed within a solenoid of much greater diameter. The iron was then raised to a high temperature by a powerful current in the platinum coils, and the heat was as far as possible prevented from reaching the solenoid by passing a stream of water between the copper cylinder and the coils. The temperature was measured by means of a thermo-electric couple contained in the cylinder. The results obtained with soft iron in fields of three different strengths are shown in Fig. 2.

COOPER'S THERMO-MAGNETIC MOTOR.

Mr. W. B. Cooper, of Philadelphia, has made a small thermo-magnetic motor, having a reciprocating action. In a letter to the New York *Electrical Review* he writes as follows :—

"A description of an experimental motor which I devised in the early part of the year 1884 may be interesting to your readers, as it is easily made and will move rapidly. It consists of a number of small radial iron wires A (Fig. 1), having a small copper wire, *a*, plaited around them to keep them in position, and secured by solder or otherwise to a vertical axis, B, their ends being trimmed to an arc of somewhat less radius than their length. A side view is shown in Fig. 2, D being a frame in which the axis moves. If the fan of wires be placed before a bar magnet, C, it will adjust itself in the horizontal plane in which it moves so that the central wires are opposite to the pole of the magnet, and if the flame of an alcohol lamp or Bunsen burner is placed under the central wires they will become heated and the fan will acquire a rapid reciprocating motion, resulting from the alternate heating and chilling of the wires above and below

Fig. 1.



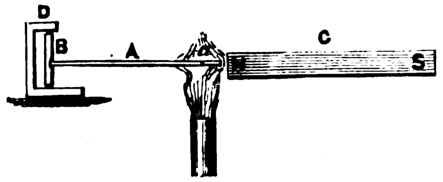


Fig. 2.

the temperature at which the critical change occurs, the ends of all the wires being at a red heat.

"To secure regular motion the flame should be completely shielded from air currents.

"A mixture of borax, glass and lime fused upon the wires will considerably reduce the oxidation."

ELECTRIC LIGHT IN STOCKHOLM.

A correspondent, writing from Copenhagen, sends us the following interesting account of the electric light in Stockholm :—

There are probably few countries where lighting by electricity seems more likely to come into use than Sweden, where one or two smaller towns are already lighted in this manner, while several others are contemplating following the example, and where a large number of factories, &c., also use the electric light. The cheap and plentiful water-power which in a great many places is available, often in the centre of the towns, or in their immediate vicinity, has no doubt something to do with this, although electric light has been adopted in many places where such favourable natural conditions do not exist.

In Stockholm there is now every prospect of soon obtaining a large central electric station, and the gasworks of the town are taking the initiative. They have recently handed in to the Corporation for their approval a plan of the contemplated electric station. The present number of electric incandescent lamps in the Swedish capital amounts to 8,300, and it has been rapidly increasing. Several matters in connection with electric light in general, its cost, &c., are touched upon in the creation from the gasworks, and it is pointed out that the town itself

Digitized by Google

ought to build the central station. Stockholm consists of several separate districts; the electric station in question will be in the part called "Norrmalm," but it is not improbable that a second station would be wanted before long in another portion. Another reason for building an electric station is the fact that new gasworks will perhaps become necessary in a few years if the town goes on increasing. Tenders for the intended installation have been invited from five firms in England, Germany, and Austria, on all the three principal systems; preference is given to the offer from Siemens and Halske, which to a great extent coincides with a project by the engineer of the gasworks, although incurring a somewhat increased cost. The price per lamp per hour is proposed to be fixed at $4\frac{1}{2}$ öre (1d. equals $7\frac{1}{2}$ öre); the number of hours per lamp per annum is put at 700. Taking interest at 4 per cent. and an annual writing off of 7 per cent., the installation is calculated to leave a profit of 27,000kr., or about 4·3 per cent. in excess of the interest on the whole capital. The central station is intended for 8,000 sixteen-candle incandescent lamps, although it may not be considered necessary to start with boilers, engines, &c., for the whole of this at once. The total cost is put at 623,000kr. (or about £35,000); boilers, engines, pumps, &c., are calculated at 119,200kr.; wires, with the necessary works, &c., at 113,900kr.; engine house, chimney, &c., 70,500kr.; site, 180,000kr., &c. The gasworks have already received applications for 4,052 lamps (from 164 consumers), of which 1,460 were for shops, 705 for offices, 533 for cafés and restaurants, 530 for school rooms, 214 for workshops, 498 for private residences, and 112 for staircases and entrance halls.

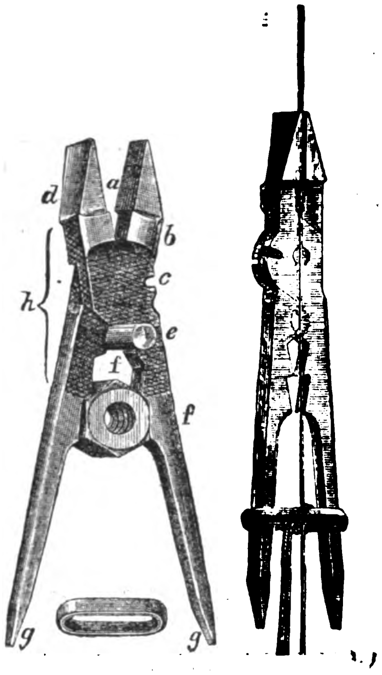
The General Post Office at Stockholm has just had electric light installed in all its different departments. There are two 30 horse-power boilers and two 20 horse-power engines with automatic expansion, and two compound dynamos. The lamps number about 350, and they can be fed from either of the dynamos. The boilers and engines have been supplied by Munktell's well-known engineering establishment at Eskilstuna, while the lamps, &c., have been supplied by the firm of Luth and Rosén, Stockholm.

The well-known firm of J. E. Ericson's Mekaniska Verkstads Aktiebolag, Stockholm, has just secured the contract for the lighting of the Swedish Houses of Parliament by electricity. The installation comprises both arc and incandescent lamps. The chambers of the two Houses are to be lighted by the former, of which there will be four in the first and six in the second Chamber. Several of the other apartments will be lighted by over one hundred incandescent lamps. A portable engine will supply the motive power. The contract is only for one year in the first instance, and the price has been fixed at 6kr. (6s. 8d.) per hour for the ten arc lamps, and the same sum for the whole of the incandescent lamps. The gas will in the meantime not be done away with. In Malmö, Sweden, three factories have quite recently had electric light laid on. At the Sconian Cement Works and at the Malmö Cloth Manufacturing Company the installations have been undertaken by the firm of Messrs. Calvert and Co., Gothenburg, while the third establishment, Mr. H. C. Olsson's copper works, has seen to it itself. Even in some Swedish villages there is some talk about electric light; for instance, those in the proximity of the Hammarfors waterfall, which would furnish the necessary power.

THE ERECTION OF OVERHEAD WIRES OF COPPER OR BRONZE.

The erection of overhead wires of copper and phosphor or silicium bronze involves a mode of operation which is somewhat different from that employed for iron wires. The following information is largely taken from a pamphlet issued by the firm of M. Lazare Weiller and Co., of Angoulême, and is issued by them solely in connection with silicium bronze wires, although it is evidently equally applicable to phosphor bronze and copper wires of small diameter.

Owing to the relative lightness and superior tenacity of bronze, compared with iron wires, it is possible to make use of less substantial supports and to employ longer spans, and the tools made use of may be of a lighter description. On the other hand, the linemen sometimes find greater difficulties in their work as their position upon the post or ladder is less well assured. It is therefore advantageous to employ as few tools as possible, and these should be easily manipulated. Such considerations have led to the design of some special



FIGS. 1 AND 2.

appliances for use with bronze wires which are due to M. J. B. Griëf, of Vienna. Fig. 1 shows his special pair of pliers.

a Ordinary pliers with smooth face.
b Pincers for small wires.
c Cutting pliers.
d Pincers for holding wires with aid of ring. (The slot in which the wire lies is seen in Fig. 2.)
e Key for screwing up insulators.
gg Screw-drivers, two sizes.
h File.

Fig. 2 shows the mode of holding a wire by means of the ring, to which is attached a cord fastened to the support.

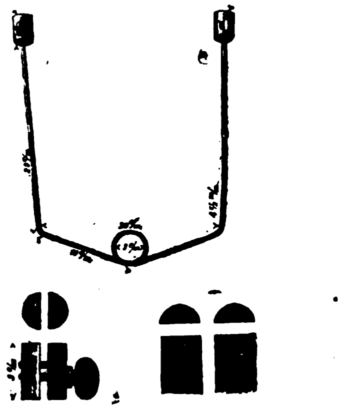


FIG. 3.

The Griëf apparatus for making joints in small wires consists of a spring fork provided at each extremity with a binding screw opened by a winged nut. This is represented in Fig. 3; it enables the ends of the two wires to be brought together without the chance of injurious bends or flexures, and permits a joint to be made with great ease.

Digitized by Google

The mode of employing the fork is represented in Fig. 4. A piece of wood of triangular section is attached to the post by means of a cord, and to this the fork is secured, as shown in the figure. For wires of large calibre, either the Britannia joint or one made with a separate coupler is preferred, but for wires of less than 1·5mm. diameter the "Weiller" is recommended. The method of making this joint is exemplified in Figs. 5, 6, 7, 8, 9, 10, 11, which are so clear as to need no further description. The length of the ends wrapped around varies with the size of the wire, about 30 to 40 c.m. are usually made use of.

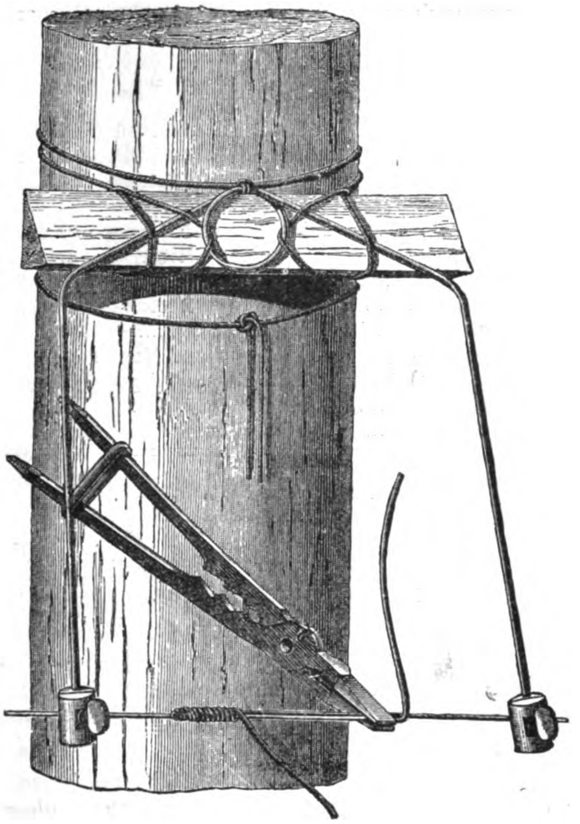

Fig. 4.

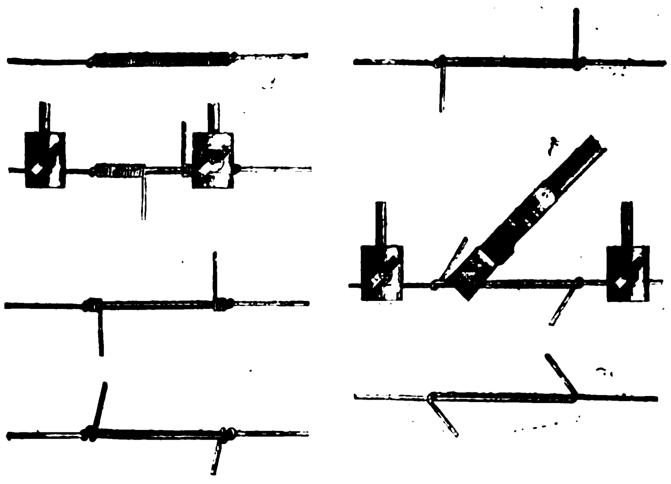

Figs. 5, 6, 7, 8, 9, 10, and 11.

The following tables show the sag allowed for some of the silicium bronze wires. Wire A_1 has a breaking strain of 44 to 46 kilogrammes per sq. mm., and a conductivity of 97 to 99 per cent. A_2, which is suitable for telephony, has a breaking strain of 80 to 86 kilogrammes per sq. mm., and a conductibility of 43 to 45 per cent. The elongation does not exceed 1 per cent.

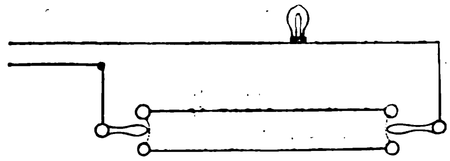
ARRANGEMENT OF INDEPENDENT SWITCHES FOR ONE LAMP.

It is occasionally required to switch a lamp, or group of lamps, in or out of circuit from either of two points. This has been done hitherto by the use of two very complicated magnetic switches; but the following exceedingly simple and neat solution of the problem was recently described in *L'Electricien*:—*a* and *b* are two two-way switches. It will be seen on inspection that if either be switched across to the other contact it puts the lamp out of circuit. Then, if again either is switched over it puts the lamp on once more.



MEETINGS OF SCIENTIFIC SOCIETIES.

(Week ending Thursday, 26th January.)

TO-NIGHT (FRIDAY), January 20th.

Royal Institution.

9 p.m. Lecture, "Diffraction of Sound." By the Right Hon. Lord Rayleigh.

SATURDAY, January 21st.

Royal Institution.

3 p.m. Lecture, "Experimental Optics." By Lord Rayleigh.

MONDAY, January 23rd.

Inventors' Institute.

8 p.m. Ordinary Meeting.

TUESDAY, January 24th.

Institution of Civil Engineers.

8 p.m. Ordinary Meeting. Paper, "The Jubilee Bridge over the River Hooghly." By Sir Bradford Leslie.

Royal Institution.

3 p.m. Lecture, "Before and After Darwin." By Mr. Geo. J. Romanes, M.A., &c.

WEDNESDAY, January 25th.

Society of Arts.

8 p.m. Ordinary Meeting. "Theatres and Fireproof Construction." By Mr. Walter Emden.

THURSDAY, January 26th.

Society of Telegraph-Engineers.

8 p.m. Meeting. Discussion on the following Paper, "On Safety Fuses for Electric Light Circuits, and on the Behaviour of the Various Metals usually employed in their Construction." By Mr. Arthur C. Cockburn, F.C.S., Associate.

Royal Institution.

3 p.m. Lecture, "My Visits to America." By Mr. H. Herkomer.

Royal Society.

4.30 p.m. Ordinary Meeting.

"The Electrician" in America.

"THE ELECTRICIAN" *can be obtained in America from* D. VAN NOSTRAND, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not ater than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

THE ELECTRICIANS' DIRECTORY.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY IS NOW READY.

NOW READY.

Volume XIX. of "The Electrician," strongly bound in cloth, is NOW READY, price Ten Shillings and Sixpence.

Cases for binding "The Electrician," price Two Shillings, Now Ready.

1887.

(Concluded.)

Post Office Telegraphs.

Perhaps the most striking fact connected with the Postal Telegraph System of this country during the past year is the quite inconsiderable amount of additional wire erected for the accommodation of the enormous and constantly-increasing traffic. With the exception of the new copper line from London to Ireland, and the necessary extensions to embrace minor outlying districts in the provinces, the mileage of working lines remains pretty much what it was in 1886. How, then, has the additional traffic with which the existing wires is now encumbered been dealt with? Mainly, and we might almost say exclusively, by improvements in the electrical appliances, the perfection of which is every year augmenting the capacity of the wires without adding to their number. The working staff has to be increased, and the apparatus multiplied; but the costly operations of erecting fresh wires is avoided, and postponed almost indefinitely by the care and thought bestowed upon the instruments, and by experimental investigations to determine more exactly the idiosyncracies of each individual line, and the possibilities of manipulating the signalling current so as to get the highest possible speed out of it. On the new Irish wire just mentioned, the duplex method has been adopted, and a speed each way of 230 words a minute, or a total of 460, has been already attained with the automatic system. This speed, however, is largely attributable to the employment of copper for the conductor, a circumstance which has led to some highly important revelations in practical telegraphy, the self-induction of the copper wire having been found to be virtually *nil*. This new fact in telegraphy and its practical application we owe to Mr. W. H. PREECE. Much regret is expressed by the administration that this discovery is for the present rendered almost valueless by the abnormal rise in the price of copper, the use of which for telegraph lines would otherwise have been greatly extended. Mr. PREECE concluded one of his papers at the British Association meeting last year with the remark that "the virtual absence of electro-magnetic inertia in copper wire is leading to its extensive adoption for telegraphy, and no other wire should ever be used for telephony." But this was said when copper

Digitized by Google

was at half its present price. The effect of its enhanced cost, however, will be probably to spur the electrical department to fresh expedients for coping with the increasing traffic on iron wires. Already the introduction of high-speed repeaters and the use of shunted condensers have raised the average rate of transmission almost to the limits of the capacity of the staff, 450 words a minute being reached with ease on circuits of 200 miles in length, and on some circuits as many as 600 words. Beyond that distance the rate would fall off proportionately but for the introduction of the fast-speed repeater at intermediate distances, which enables the communication between such places as London and Dublin, London and Glasgow, and even Aberdeen, to be maintained at the highest speed. This high-speed repeater is said to owe its efficiency to the perfection of the Post Office standard relay—a relay which has practically no time-constant, which responds to exceedingly delicate currents, and which makes perfect electrical contacts—and to the use of condensers. Repeaters have been introduced on forked news wires, so that offices on separate branches of a circuit worked as one can communicate with each other and with the terminal office without interrupting each other's signals. By means of a repeater at Leeds the Delany multiplex system has been found practicable to Glasgow, and by a similar device Scarborough and its sub-offices are working multiplex to Leeds. Some valuable results have been obtained by the employment of condensers on land lines with the object of making the signals clearer; and it is intended to do away with the intermediate sounder on quadruplex circuits by making use of the extra current of the cores. A new key has been designed for multiplex working, and several improvements made in the testing galvanometers, as well as in the relays to increase their sensibility. Some experiments are in progress for determining the time-constant of electromagnets in relays, which it is believed will lead to very useful results for practical telegraphy. Turning to the less important instruments of the service, the single needle has been fitted with tin sounders, which have the effect of converting the needle into an acoustic receiver. On its underground system the Post Office have lately adopted a new core for its cables, the copper of which is much heavier in proportion to the gutta percha insulator than heretofore. They have also devised an improved method of testing "seconds," or restored gutta percha covered wire with a view to increase its durability by eliminating incipient faults before laying. Of the Post Office Telephone System we need say very little; wherever it is working it is confessedly excellent in every particular, except perhaps in extent, for in reality the department seems to have ceased to make even a show of competing with the companies, who consequently have the field almost all to themselves. Nevertheless, the public are gainers by the Post Office's indefatigable efforts to improve the telephone and its accessories as an electrical speaking instrument. The distance at which induction can be felt on telephone wires has been determined with tolerable precision; and the limits of audibility being ascertained, the current necessary to produce an audible signal on the Bell telephone has been calculated. It has also been found that the possibilities of long distance underground telephony, when suitable copper wire is employed, are far greater than at first was imagined. Full particulars of these investigations having been communicated to the Royal Society and British Association last year, and published in our columns at the time, we need not repeat them now. It is sufficient to note that the public reap the advantage in the creation of a high standard of efficiency by the Post Office Telephone Service, at which standard the companies must continually aim in order to retain their hold on public favour. The number of telephone instruments actually in use under Post Office control at the end of the year was 4,481, being an increase of 366 on the corresponding period 1886. Except in respect to the telephone, no exact information is available down to the close of 1887. Nine months ago, however—that is to say, at the end of the financial year, 31st March, 1887—the total length of telegraph lines, overhead, underground and submarine, worked by the Post Office in the public service was 27,935¼ miles, representing 156,220 miles of wire. These figures do not include wires which are rented from the department for private use, and which represent a mileage of 17,318¾. At the date mentioned above the Post Office possessed 1,540½ miles of submarine cables, the wiring of which was equivalent to 5,050¼ miles. In regard to apparatus, the total number of instruments actually in use was 11,530. Of these 3,040 were sounders, which are rapidly displacing the Morse printer. There were 398 fast-speed automatic instruments in operation, exclusive of multiplex apparatus; and 105 repeaters. The pneumatic system, connecting some of the principal offices in London and other large towns at the date referred to, measured 46¾ miles. We may mention in concluding this review of the work of the Post Office Telegraphs that the central hall of the chief office in London and various other rooms in the building are now fitted with the electric light.

Cables.

POST OFFICE.—The cable operations of the Post Office during the past year have been confined to the maintenance of existing cables, which, for the most part, have suffered no serious damage. Of the Companies' cables there are few operations of any kind to record; but the following particulars may be of interest, relating to

THE EASTERN TELEGRAPH COMPANY.—The most important cable operation of this company during the past year was the laying of a duplicate cable from Porthcurnow to Malta; and also a direct cable from Malta to Zante. The lengths are given below:—

		Nautical Miles.
Porthcurnow	to Lisbon, No. 2	891
Lisbon	„ Gibraltar, No. 2	337
Gibraltar	„ Malta, No. 2	1,126
Malta	„ Zante	374
		2,728

In February the ss. "Electra" connected Gibraltar with Tangier, 33 nautical miles. On the 18th April, before daylight, the ss. "Volta" struck on the north coast of Mykonos Island, in the Levant, and became a total wreck. The captain, two assistant electricians, and eight of the crew were lost. During the month of November the ss. "Mirror" laid a duplicate line between Zante and Patras, 58 nautical miles. A new ship, to be named the "Amber," is being built at Messrs. Napier's, Glasgow, to replace the "Volta," and was successfully launched yesterday, as will be seen by the account which we print in another column.

The Telephone.—*(Concluded.)*

THE EQUITABLE TELEPHONE ASSOCIATION.—The following details of the work of this company are given as supplementary to our last week's article on the telephone in 1887:—

The Equitable Telephone Association has adopted the principle of selling their telephones outright, and charges a small annual fee for maintenance when required. The success of this system is evidenced by the fact that though the Associa-

Digitized by Google

tion has only just completed the first year of its existence a large number of the "Swinton" telephones are now in use in various parts of the country, and are employed by such eminent firms as Messrs. Sir W. G. Armstrong, Mitchell and Co., of Elswick; the Bute Docks Company; Messrs. Tancred, Arrol and Co.; the Co-operative Wholesale Company, and many others. Since the "Swinton" telephone was first described in *The Electrician* (June 10, 1887) several modifications have been introduced in the form of the instrument. One of these—a cheap and simple form of telephone, suitable for use as a substitute for speaking tubes and mechanical telephones over short distances—was placed on the market in October last, and has met with a great measure of success. It will be remembered that the original Swinton instruments worked with direct-battery currents without induction coils. This arrangement, though it answers very well for short circuits, has several disadvantages on lines of considerable resistance and for exchange systems, and the Association has therefore recently introduced a modified instrument for long distances in which induction coils are employed. Messrs. Sir W. G. Armstrong, Mitchell and Co., of Elswick, have had a pair of these new instruments working on a three-mile line of iron wire for some time, and report that they are giving satisfaction.

LAUNCH OF A CABLE STEAMER.

Yesterday (Thursday) afternoon Messrs. R. Napier and Sons launched from their shipyard at Govan the telegraph cable steamer "Amber," for the Eastern Telegraph Company.

The vessel has been specially designed by Mr. Joseph Birnie, London, for laying and repairing the company's submarine cables, and while externally the steamer has the appearance of a Trinity yacht, internally the arrangements are of the most complete character for the difficult and delicate task she is intended for.

Besides the usual appliances of a first-class modern steamer, the vessel is fitted with large circular tanks for holding the telegraph cables, and has been sub-divided into numerous watertight compartments for trimming and ballasting purposes. Her dimensions are—length 210ft., breadth 31ft., depth 24ft., classed 100 A1 at Lloyd's under special survey. Very complete and comfortable accommodation has been provided for the large staff of officers, electricians, and crew, with the necessary chart house and testing room, which will be fitted with the best instruments for the task the vessel will be engaged upon. The bow sheaves give the vessel a peculiar appearance, but they have been wrought in by the builders in an ingenious way to form part of a clipper bow, which adds to the symmetry of the design.

The machinery will consist of triple expansion engines, which have been constructed at Messrs. R. Napier and Sons' Lancefield Works, under the supervision of Mr. Beldam, London.

In the absence of the Marchioness of Tweeddale, who was to have christened the vessel, the ceremony was performed by Miss Agnes M. Hamilton, who named her the "Amber" as she left the stocks.

After the launch Mr. KIRK proposed "Success to the newly-launched vessel," mentioning that this was the fifth vessel they had launched for the Eastern Telegraph Company. Mr. JOSEPH BIRNIE briefly replied on behalf of the Company. Mr. R. M. RENWICK proposed "The Health of the Builders," Messrs. Napier and Sons, whose ability to build cable ships had been so often proved that it was not likely the Eastern Company would find better builders anywhere.—Mr. JAMES HAMILTON replied for the builders, and hoped that their connection with the Eastern Telegraph Company might long continue.—After a vote of thanks to Miss Hamilton the proceedings closed.

CENTRAL STATION INDICATING INSTRUMENTS OF THE EDISON COMPANY.

The following account of the indicating instruments employed by the Edison Company of America is taken from our New York contemporary, the *Electrical World*:—

For incandescent lighting it is necessary to maintain a constant pressure on the circuit. In any plant the pressure is fixed by the lamps used, and it is necessary to keep the pressure invariably at this point, and no other pressure concerns the attendant in the least. The engineer should have a pressure indicator which enables him to see readily *from a distance* whether or not the pressure is right. A zero instrument enables him to do this, as when the pressure is right the pointer is at zero, in the middle of the scale, and a change of one volt may deflect the pointer half an inch or an inch from zero if desirable. Such small changes in voltage may be easily seen from a distance and the pressure be kept right.

The pressure indicators used by the Edison Company are all zero instruments; they can be adjusted for the pressure used in any plant, and the divisions on the scale in front of which the pointer swings are ⅞in. apart; and to deflect the pointer over one of these divisions requires a change of two volts in the pressure on the line.

The Edison Company have for some time been using a number of instruments for this purpose, built at the Edison lamp works at Harrison, N.J. These instruments embody a variety of principles in their operation, but it will be noted from the descriptions that follow that nearly all are designed on the zero method of

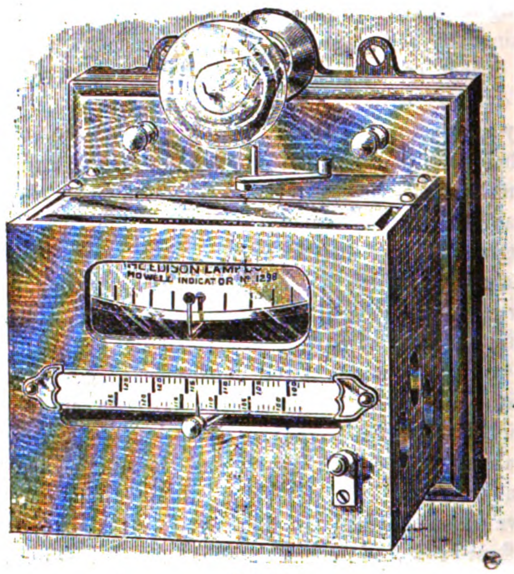

Fig. 1.

indication. By adopting this principle the use of springs, electromagnets, or permanent magnets as acting forces is avoided. The permanent magnet employed in the instruments is in the shape of a needle, which indicates the true reading only when in a neutral position—that is, when it is not acted upon, or is in equilibrium. These instruments include for the most part apparatus for measuring the potential or pressure carried on the circuit, as this is evidently the principal point to be considered in the operation of incandescent lights. We propose to describe these various instuments, and shall begin with the standard pressure indicator.

This instrument is shown in perspective in the engraving, Fig. 1, and by its means all variations in pressure are immediately indicated.

The principle upon which the action of the indicator depends is the great variation in the resistance of a carbon filament due to change of temperature. The circuit to be measured is made to act upon the carbon filament, sending a current through it, and the amount of current which flows through the filament is determined by the pressure on the circuit and varies with this pressure. The temperature of the filament varies with the current, and so also does its resistance. Hence, by measuring the resistance of the filament at any time, we measure indirectly the pressure or potential acting upon it. The indicator is simply a Wheatstone bridge arrangement, by which the resistance of the filament is measured when a current is flowing through it. Although in reality the resistance of the carbon filament is measured, the marks upon the scale give the volts or pressure necessary to bring the carbon to that resistance, and hence such a scale gives a direct measure of the pressure of the circuit.

Digitized by Google

The diagram, Fig. 2, shows the essential details of the indicator. Here L represents a high resistance lamp, giving the necessary high carbon resistance, and D is a coil of wire heavy enough to carry the lamp current without heating too much. These two resistances form one arm of the bridge. The other arm is made up of three wire resistances, A, C, and B, and the galvanometer is connected between the point F and the frame upon which the sliding contact S slides. This enables the galvanometer contact to be made at any point of the resistance C. If A plus that part of C on the left hand side of the galvanometer contact be represented by A′; and B, plus the part of C on the right hand side of the galvanometer contact be represented by B′, then, when the bridge is balanced and no current flows through G, we have A′ D = B′ L. G is a simple galvanometer which shows the direction and relative amount of the current flowing through it; when the hand is on zero no current is flowing in G.

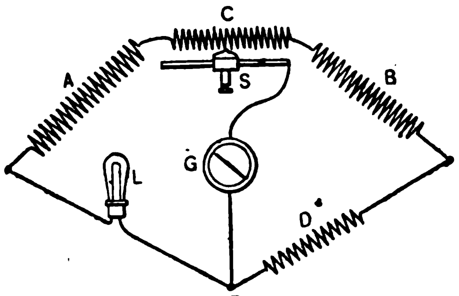

Fig. 2.

Now, if the sliding contact be in the centre of resistance C and a suitable lamp be in L, on sending a current through the indicator and gradually increasing it the resistance of the filament becomes less and less, until, when the desired pressure is acting upon the indicator, we have A′ D = B′ L. No current flows in G, and the pointer remains on zero with the circuit either made or broken. This position of the sliding contact is marked to indicate what this pressure is, and if at any time the contact be placed at this point and the pressure made such that there is no current in G, it is evident that the indicator shows the same pressure as that employed when it was adjusted at that point. The indicator being thus balanced, if the pressure be increased the pointer will move to one side of zero; if it be decreased it will move to the other side.

If now the sliding contact be moved to some other point it will alter the values A′ and B′, and the pressure will have to be changed until the resistance of L is changed enough to make A′ D = B′ L again. This position of S, corresponding with the new pressure, can be marked, and in this way can be found the pressures that will balance the bridge with the contact S, in any position on the coil C. Thus the scale can be marked for a range of volts. The pressure of the circuit can then be set at any point that is on the scale, and changing the pressure on the line until the bridge is balanced and the pointer remains at zero, with the galvanometer circuit either open or closed.

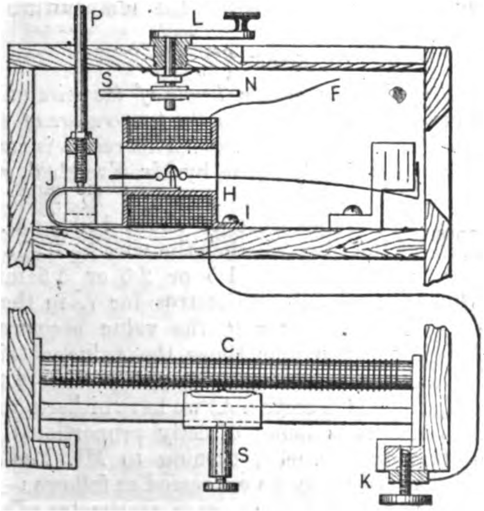

Fig. 3.

The upper half of Fig. 3 shows the galvanometer in section, and below is shown the resistance C and the sliding contact S, which makes the galvanometer contact at any point of the resistance. The magnetic needle in the galvanometer consists of two pieces of steel wire, one on each side of the jewel centre; the steel point upon which the needle swings is fixed to a brass support, H. The spring J is normally in the position shown in the illustration, being held down by the pin P. If the latter be raised by unscrewing it, the spring J will rise and lift the needle off its steel supporting point, and hold it against the frame of the galvanometer. This is done whenever the indicator is carried about or handled; otherwise the steel point might become dull or be broken. The directing magnet, N S, overcomes the earth's magnetism and makes a magnetic field for the galvanometer, which enables the pointer to be brought to zero, whatever the position of the indicator; the directing magnet may be moved one way or the other by the lever L. The galvanometer circuit runs from F (Fig. 3), through the galvanometer, through the switch to the metal frame on which the sliding contact travels, and through the sliding contact to the point of contact on resistance C. The switch is a simple screw connecting the brass block K, to which the galvanometer wire is fastened, to the metal frame carrying the sliding contact. When the screw is withdrawn one or two turns, so that it no longer touches the frame of the slider, the galvanometer circuit is broken. The upper part of the box, which contains the galvanometer, is separated from the lower part, which contains the resistances, by a wooden partition, to which the galvanometer and scale are fastened.

Fig. 4 shows the connections of the indicator as they exist in the instrument, the coils, however, being shown separately. These connections, four in number, are shown in the order in which they exist in the indicator.

The resistances A, B and D are wound upon one wooden spool, which is placed on the lower part of the box under the partition. This space is ventilated through the sides and bottom, front and back of the box; the spool is also made so that the wire upon it is well ventilated. The resistance C and the frame carrying it and the

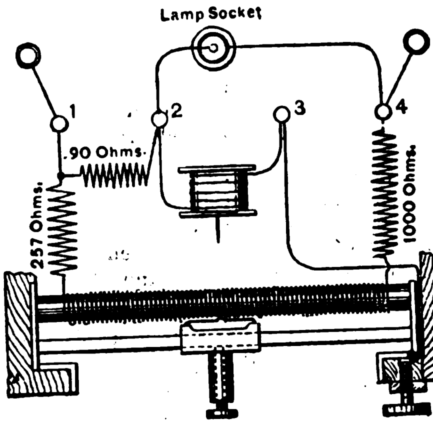

Fig. 4.

sliding contact are placed in the lower part of the box. The handle by which the sliding contact is moved projects out through a slot in the front of the box so that it can be easily moved.

The lamp forming the high-carbon resistance is screwed into a socket on the base of the indicator just above the box holding the galvanometer and resistances. Half of the top of this box is of glass, so that the light from the lamp shines through the glass upon the back of the paper scale, in front of which swings the end of the hand or pointer of the galvanometer. This paper scale being translucent allows enough light to pass through it to enable one to see the pointer and scale readily.

The indicator is so constructed that its readings are correct for all temperatures. This is effected by making the coils A and D of German silver wire, and the coil B partly of German silver and partly of copper. By suitably proportioning these parts the indicator remains balanced at any temperature.

A lamp that has been tested and sent out with an indicator is not likely to change, and experience shows that they remain constant for a very long time. Nevertheless, to correct any possible change in a lamp an extra lamp is sent with each indicator. Of these two lamps only one can be used at any one time, and points are marked on the scale for each lamp.

It will also be noticed that, as shown in Fig. 1, two scales are marked on the indicator. These are respectively drawn in red and black ink, and the lamps sent with the indicator are marked with red and black to correspond. The object of this is to afford a means of checking the accuracy of the readings by employing one lamp solely for the purpose of comparison, which is used but seldom, and whose resistance, therefore, does not vary. The other lamp is employed continuously, and any variation in its resistance is shown when compared with the standard lamp.

In isolated plants the indicator is connected either to a part of the circuit where lamps are connected, and if possible to a circuit

Digitized by Google

where lamps are burning most of the time, or to the centre of distribution, if there is only one such centre. In the latter case it is necessary to set the indicator for a pressure higher than the lamp pressure by the loss from the centre of distribution to the lamps. Thus, if in 103-volt plant the loss from the centre of distribution to the lamps is 3 per cent., the indicator is set for 106 instead of 103 volts, since the pressure indicated is that at the indicator itself.

In central stations using comparative indicators three pressure indicators are employed. Two of these are connected to the pressure wires from the end of the standard feeder, and one is used as a standardising indicator to adjust the first two at any time. The two regular pressure indicators, being connected to pressure wires, cannot be standardised properly before sending out, as the pressure wires are in circuit with them, and the pressure at the indicator is the pressure at the feeder end, less the drop on the pressure wires ; and as this drop is an unknown quantity, it cannot be allowed for until the indicators are connected in the drop to be measured. No scale is therefore marked on these two indicators. The third or standardising indicator used in connection with central stations has a scale marked on it, covering a range of about 15 volts. In using this indicator it is put in circuit in place of either one of the two regular pressure indicators, to tell whether these have changed in any way. This is accomplished by means of the switch shown in Fig. 5. P P are the two pressure indicators, and S is the standardising indicator. When the arms of the switch are in the position shown in the diagram the two pressure indicators are in circuit, but the standardising indicator is not in circuit. Throwing the arms of the switch on either side cuts one of the pressure indicators out of circuit, and throws the standardising indicator in circuit in its place. When used in this way the reading on the standardising indicator should be less than the pressure it is desired to maintain at the feeder ends by the drop in the pressure wires. If these pressure wires are copper wires (about No. 12), this drop is negligible, and the standardising indicator should balance at the feeder end pressure. If, however, the pressure wires are iron, the drop is often four or five volts, and must be allowed for. In this case the standardising indicator should be balanced at four or five volts lower than the feeder pressure. This drop is determined by the voltmeter.

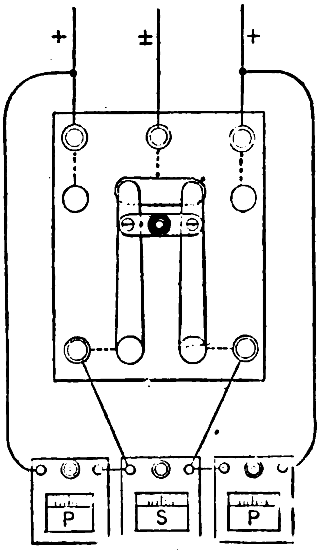

Fig. 5.

THE SWINTON SWITCH-BOARD FOR PRIVATE TELEPHONES.

We illustrate herewith a simple and effective arrangement devised by Mr. Swinton, of the Equitable Telephone Association, in order to dispense with the necessity for a central exchange in cases where the telephone is used as a substitute for speaking tubes in hotels, factories, warehouses, or other buildings. Where speaking tubes are employed in order to speak from any one station to any other, it is obvious that for n stations $\frac{n(n-1)}{2}$ separate tubes are necessary ; but in this system the same end is attained with only $n+2$ wires. The connections are shown in the adjoining figure. A small switch-board is attached to each instrument, and a flexible cord is provided with a plug which is inserted in the plug-hole corresponding with the station required. It will be seen that the left-hand plug hole of each switch box is marked with the letter that denotes the individual station to which this switch-box belongs. Z and C are the wires connecting the various switch-boxes to the zinc and carbon terminals of the battery, and 1, 2, 3, 4 are the four line wires that are necessary to connect the various switch-boxes together. The terminals of the boxes are numbered, and and all bearing the same number are connected to the same wire. When the telephones are not in use the receivers are all hung up on their respective switch-hooks, and the plugs are inserted in the left-hand plug holes of the several switch-boxes. Thus the plug belonging to A is inserted in the hole marked A, that belonging to B in hole B, and so on, as shown in the illustration. Supposing A wishes to communicate with C, he has only to remove his receiver from its hook, remove his plug from the hole marked A of his switch-box, and insert it in the hole marked C, to cause the call bell at C to ring, the ringing of the bell notified to A by the noise in his telephone receiver, due to the contact breaker of the bell at C.

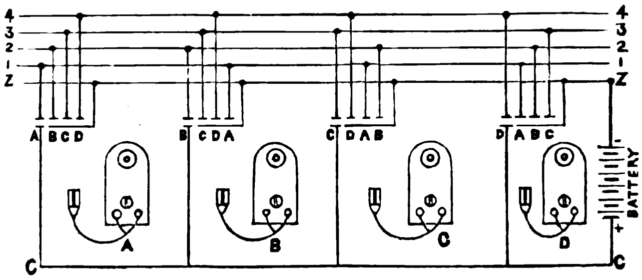
On C removing his receiver from its hook the noise ceases, and A knows that he can talk to C and *vice versâ*. When the conversation is completed A replaces his plug in the A hole of his switch-box, so that other stations may be able to call him up if required.

In a similar manner any one of A, B, C, D can call up and carry on a consersation with any other, and A and B can talk together while C and D are doing the same, or any other combination can be effected.

If, however, B tries to call up A or C while the latter are conversing with one another, their bells being now out of circuit, the absence of the rattling noise in his receiver on his attempting to call attention intimates to B that the line is engaged. This prevents interruptions of conversation and any possibility of confusion.

The above examples show the principles of the system when applied to four stations, but of course, the switch-boxes can be made with any number of plug holes for a system comprising any number of stations ; and when it is convenient that only some of the stations should have the power of calling up all the others, only these particular stations need have switch-boxes containing the full number of plug holes, and be connected with the full complement of wires.

We have recently inspected an installation of this character in the city, and found the arrangements to answer every purpose for which they are designed. In another building a set of twenty-seven telephones are being fitted on this system. We fully anticipate that a considerable demand will arise for Mr. Swinton's simple and ingenious device.



The Swinton Switchboard.

PORTABLE VOLTMETERS FOR MEASURING ALTERNATING POTENTIAL DIFFERENCES.*

BY W. E. AYRTON AND JOHN PERRY.

(*Continued from page 244*)

B.—Waste of Power in the Voltmeter.

From the equations previously given it follows that the waste of power in watts spent in keeping a long fine wire l_0 centimetres in length $\theta°$ C. above the temperature of the surrounding space equals

$$0{\cdot}0008848\,\pi\,l_0\,\theta,$$

a value which depends only on the length of the wire and on the temperature to which it is raised above the temperature of the case, but not at all on the diameter of the wire. This result is confirmed by the experiments recently made by Mr. Evershed, who has found that about 36 watts are required to keep a wire 3,600mms. long at a temperature of about 180deg. C. above the temperature of the case, whether the wire be 0·038mm. or 0·0635mm. or 0·0889mm. (*i.e.*, 1·5 or 2·5 or 3·5 mills.) in diameter. Substituting 360 centimetres for l_0 in the above expression, and 180deg. C. for θ, the value becomes 180·2 watts. This is more than four times the value obtained by Mr. Evershed, and the reason may be partly due to the fact that (as already noticed in section A) we have hitherto regarded the rate of loss of heat as being directly proportional to the difference of temperature. On turning to Mr. McFarlane's paper we find his result may be expressed as follows :—

Loss of heat per second per square centimetre of a bright copper ball 2 centimetres in radius for a difference of temperature $\theta°$ C.

$$= \text{Loss for 1deg.C.} \times \theta \left(\frac{0{\cdot}000168}{0{\cdot}000170} + \frac{1{\cdot}98}{{\cdot}000170} \times 10^{-6}\,\theta - \frac{1{\cdot}7}{{\cdot}000170} \times 10^{-8}\,\theta^2 \right).$$

Instead, therefore, of writing as above the expression for the rate of loss of heat in watts required to maintain a long wire l_0 centimetres in length at a temperature $\theta°$ C. above that of the surrounding space, it will probably be more correct to write it as something like

$$0{\cdot}0008848\,\pi\,l_0\,\theta\left(\frac{0{\cdot}000168}{0{\cdot}000170}+\frac{1{\cdot}98}{{\cdot}000170}\times 10^{-6}\,\theta-\frac{1{\cdot}7}{{\cdot}000170}\times 10^{-8}\,\theta^2\right).$$

If now we substitute 360 centimetres for l_0 in this expression, it becomes

$$\theta\,(0{\cdot}9883+0{\cdot}01165\,\theta-10^{-4}\,\theta^2)\text{ watts.}$$

Of course we cannot expect this expression to give absolutely correct results for any values of θ, seeing that Mr. McFarlane's experiments did not extend beyond θ equal 60° C. The expression is interesting, however, as showing that, in consequence of the negative term, ϵ must be taken as having a smaller value when θ is high than when θ is low. For θ equal to 180° C, which was about the excess temperature of the wire in Mr. Evershed's experiments, the formula as it stands cannot be applied, as it leads to a negative answer; but for θ equal to 164·5° C., it gives, as it happens, almost exactly 36 watts, the power Mr. Evershed found was expended in any one of the three wires he tried.

Mr. Evershed informs us that he estimates the temperature to which the wire is raised by measuring its expansion; we, on the other hand, have found it more convenient, with our form of voltmeter, to estimate the rise of temperature of the wire by measuring its increase of resistance. Employing this latter method we find that, roughly, 3·5 watts per foot are necessary to maintain a very fine platinum-silver wire at a temperature of 200deg. C. above that of the case. This result is rather higher than that obtained by Mr. Evershed, and corresponds with a value of ϵ equal to about $\frac{0{\cdot}0002}{d}$.

In the absence of the results of experiments made for many values of θ it is impossible to say what is the exact function of θ that ought to be employed in the expression for the watts, and consequently we are at present engaged on experiments for determining this function; from what we have given, however, there is reason to think that the expression for the watts required to be spent in maintaining a long fine wire at any temperature θ above that of the surrounding space is a function of the length of the wire and the excess temperature only, and is nearly, if not entirely, independent of the diameter of the wire.

C.—The Range in Volts.

If θ_1 be the highest temperature of the wire allowable; if V_1 volts be the range of the instrument without using external resistance coils, then, from (4),

$$V_1=2\,l_0\sqrt{\frac{\epsilon\,\rho\,\theta_1}{d}}\quad\ldots\ldots\quad(10)$$

so that this range is proportional to l_0—that is, to the length of wire through which the current passes in going from one terminal to another of the instrument. Hence, if there are 10 wires, each of length λ_0, we can make $l_0=10\,\lambda_0$ by placing the wires in series, or $l_0=\lambda_0$ by placing them in parallel by means of a commutator.

Since, for small wires, ϵ is inversely as d, the range in volts increases directly as the length of the stretched wire and inversely as its diameter. As, however, increasing the length increases the waste of power in the instrument, it is rather by diminishing the diameter of the wire that the range in volts ought to be increased.

If a small range in volts be desired, it is better, in order to avoid waste of power, to use one thick wire than several thin wires in parallel; and this rule ought to be followed as long as the thick wire is sufficiently quick in its action.

In order, however, to obtain a great range, it may in many cases be desirable to employ a many-wire voltmeter with a commutator, in spite of the fact that this arrangement does not give us the instrument that is most economical in the power wasted when a few volts are being measured.

D.—The Greatest Angular Deflection of the Pointer.

With any given spring, it is obvious that we ought to tighten the wire and adjust the initial tension in the spring until the initial pull in the wire is q—the greatest pull to which the wire ought to be subjected—and also until we find that at the highest temperature the spring is just able to keep the wire taut. In our instruments, where the wires lie nearly all parallel to one another, we have these two adjustments, and also in those with the bicycle-wheel arrangement of wires, in which the outer ends of the wires may be attached to adjustable flexible strips. For the sake of easy calculation we may take the final pull in the spring as 0. Let L be the length of the spring, ϕ_1 the deflection of the pointer when θ_1 (the highest temperature of the wire) is reached, P_0 the initial pull in the spring. By the triangle of forces

$$P_0=\frac{4\,y_0\,q}{l_0}\quad\ldots\ldots\quad(11)$$

(If there are n wires caught by the end of the spring, say n complete diametral wires in the bicycle-wheel form, then then instead of q we must use $n\,q$.)

The law of the spring is such that

$$y_1-y_0=r\,P_0\,L\frac{a}{t^3}\quad\ldots\ldots\quad(12)^*$$

where r is the radius of the coils of the spring, L its axial length, a a constant depending on the material of the spring, t the thickness of the strip of which the spring is made; and another law of the spring is

$$\phi_1=P_0\,L\frac{b}{t^3}\quad\ldots\ldots\quad(13)$$

where b is a constant like a. In fact, $\frac{b}{a}$ is the constant s used in (6).

Substituting for P_0 from (11) in (12),

$$y_1-y_0=r\,L\,\frac{a}{t^3}\,\frac{4\,q}{l_0}\,y_0=S\,\frac{r}{t^3}\,y_0,\text{ say}\quad\ldots\quad(14)$$

equation (2) is $y_1{}^2-y_0{}^2=\frac{1}{2}\,l_0{}^2\,a\,\theta_1=R$, say.

Dividing by (14), we have

$$y_1+y_0=\frac{R\,t^3}{S\,r\,y_0};$$

so that

$$y_1=\frac{R\,t^3}{S\,r\,y_0}-y_0.$$

Substituting in (14), we find

$$\frac{R\,t^3}{S\,r\,y_0}-2\,y_0=S\,\frac{r}{t^3}\,y_0,$$

or

$$y_0=\sqrt{\frac{R}{S\,\frac{r}{t^3}\left(S\,\frac{r}{t^3}+2\right)}}\quad\ldots\ldots\quad(14)$$

Substituting for P_0 from (11) in (13),

$$\phi_1=\frac{L\,b}{t^3}\,\frac{4\,q}{l_0}\,y_0\quad\ldots\ldots\quad(15)$$

and using y_0, just found, in which $R=\frac{1}{2}\,l_0{}^2\,a\,\theta_1$, and $S=\frac{4\,L\,a\,q}{l_0}$, we find eventually that

$$\phi_1=\sqrt{a\,\theta_1\,\frac{b^2}{a}\,\frac{L\,q\,l_0{}^2}{2\,L\,a\,q\,r^2+r\,t^3\,l_0}}\quad\ldots\ldots\quad(16)$$

where neither of the two terms in the denominator is negligible. The observation in brackets given after (11) tells us that we may use $n\,q$ instead of q in the formula if there are n lengths of wire or n complete diametral wires in the bicycle-wheel form of instrument. An examination of (16) will show how the range ϕ_1 may be made large.

The following are the deductions that may be drawn from (16):—

1st. If f be the working stress suitable for the material of the wire, $q=f\,\frac{\pi}{4}\,d^2$, or $n\,q=n\,f\,\frac{\pi}{4}\,d^2$;

so that, if we desire a large maximum deflection without reference to the range of volts, we ought to use wires as thick as

* "A New Form of Spring for Electric and other Measuring Instruments," Proc. Roy. Soc., No. 230, 1884, p. 311.

Digitized by Google

possible, or else use many spokes in the bicycle-wheel form. The limit to the thickness that may be given to the wires arises from the fact that the heat equilibrium will only be established slowly with thick wires, so that the dead-beat character of the instrument suffers if the wires be too thick.

2nd. The greater l_0 is, the greater is the maximum deflection. Hence the greater the diameter of the bicycle-wheel and the more numerous the spokes, the greater the maximum deflection. Also, the greater the diameter of the bicycle wheel and the greater the number of spokes, still more noticeable is the range in volts.

3rd. Diminishing the thickness (t) of the strip of metal of which the spring is made has a *very great* effect in increasing the maximum deflection.

4th. Increasing the length (L) of the spring increases the maximum deflection just in the same way as increasing q or $n q$.

5th. Diminishing r, the radius of the coils of the spring, produces a great increase in the maximum deflection.

(*To be continued.*)

CARBON AS A POSITIVE ELEMENT.*

BY WILLARD E. CASE.

[We are indebted to the Secretary of the American Institute of Electrical Engineers for a copy of an interesting paper read before the Institute on January the 10th, 1888. The following is an abstract.]

The following experiments, undertaken by the author, may be of interest as indicating the way in which the cheap generation of electrical energy may possibly be brought about.

In the first experiment, an element was formed through which heat energy was converted into electrical energy, in which the correlation of forces is beautifully illustrated.

It is a sort of voltaic battery, in which plates of tin and platinum forming the electrodes are immersed in a solution of chomic chloride, which has no action on the plates at ordinary temperature, so no current is generated. The cell is hermetically sealed, and when heated the liquor becomes active, and part of one of its elements, chlorine, leaves the chromic chloride, goes over and temporarily combines with the tin, forming a proto-chloride of tin. The chemical action generates an electric current, but soon the tin is all converted into chloride, and the current ceases. When the cell is cooled, this temporary combination of the chlorine and tin is broken up, and the chlorine returns to the chromium proto-chloride. The tin being set at liberty, falls as a metallic precipitate to the bottom of the cell in the form of beautiful crystals, ready to renew the combination when the cell is again heated. None of the materials of the elements are destroyed, they last an indefinite time. The chlorine changes from chromic chloride to tin and back as often as the cell is heated and cooled.†

It will probably be found that the solution of the tin absorbs heat, and so tends to cool the liquid, and the precipitation develops heat, and so tends to warm the liquid, and that the part where the solution occurs must be kept warmer than that where the tin precipitates. An investigation would probably show that when electric currents are generated the heat absorbed by the solution of the tin is in excess of that generated by the precipitation of the equivalent of the electrical energy developed, and that the possible excess is governed by the second law of thermo-dynamics. If the cell works between 80deg. and 180deg. F., the E.M.F. at the higher temperature is about 0·26 volt, the efficiency is less than 16 per cent., as the possible efficiency $= \frac{T-t}{T}$ reckoned from absolute zero, or $\frac{638^\circ - 538^\circ}{638^\circ} = 15{\cdot}7$ per cent. In fact, this cell is a heat engine, analogous to the thermopile, which is said to convert only 2 per cent. of the energy of the coal into electric energy. In practice probably nothing like 16 per cent. could be utilised.

By the second law of thermo-dynamics the minimum amount of heat that goes to the cooling agent is the fraction $\frac{t}{T}$ of the total amount employed, where t is the temperature of the cooler reckoned from the absolute zero and T the higher temperature of the working substance; t cannot be less than about 500 deg., so the numerator of the fraction is always large, and the heat wasted is the larger portion. Understand that this is the law of nature; it is inevitable under the conditions in which we live. No cunningly devised furnace, or feed-water heater, or cut-off, or triple expansion apparatus, or pyro-generator can save this heat. The most that any of these devices can do is to save what would otherwise be wasted over and above the proportion $\frac{t}{T}$. But are we to go on wasting all this energy of fuel? Cannot some means be employed to utilise it? We know that the voltaic battery is not a case of the transformation of heat into electrical energy; it produces electrical energy directly. The second law of thermodynamics does not apply, as no heat appears. If we could convert the chemical energy of coal and oxygen into electric energy, directly and cheaply, we would do away with all our steam motors at once. There is no known reason why a cheap substance may not be found which will act on coal and develop electric currents in place of heat. This electric energy would be the equivalent of the heat energy that would be developed by the combustion of the same coal in the ordinary way, and could be transformed into mechanical power, heat, light, &c., with small loss.

So far, little progress has been made in this direction. Some time ago Jablochkoff produced a battery in which plates of carbon and iron were immersed in fused nitre. The carbon being oxidised furnished strong currents. The objection to this element is the generation of heat through local action. To it the second law does not apply. Another battery of more interest than the first is an illustration of an element which is not affected by the second law; heat is not essential to its operation, as the energy due to the complete oxidation of carbon is converted into electric energy directly.

In a glass cell containing sulphuric acid, sp. gr. 1·81, temp. 75 F., two electrodes were immersed, one of platinum, the other of lump graphite; only a slight E.M.F. was indicated, 0·007 volt, due to the combination, the graphite acting as a positive element; on the addition of a small quantity of chlorate of potassium to the acid the E.M.F. immediately rose to 0·08 volt, the graphite being disintegrated after a time. This cell polarised rapidly, which was partially prevented by mechanical means. The reaction of chlorate of potassium with sulphuric acid may be represented by the following equation:—

$$3\,KClO_3 + 2\,H_2SO_4 = 2\,ClO_2 + KClO_4 + 2\,KHSO_4 + H_2O.$$

Potassic chlorate and sulphuric acid yield chloric peroxide, potassic perchlorate acid sulphate of potassium and water.

A method of exclusion was adopted to ascertain the oxidant of this electrolyte; chlorine peroxide (Clo_2) appeared to be the only active agent. It is decomposed by the carbon, chlorine being evolved with some oxygen. It was assumed that in this cell graphic acid ($C_{11}H_4O_5$) was formed as the result of the chemical actions. There is probably much waste of energy through local action, as the chemical reactions go on when the circuit is open, but to a less extent. In another experiment an electrolyte was formed of sulphuric acid and chlorine peroxide*, the gas being formed in a retort by the action of sulphuric acid on chlorate potassium, and conducted over into the acid in which it was dissolved. This cell, with a positive element of graphite, opposed to platinum, gave an E.M.F. of 0·7 volt.

A similar combination was used with a solution of chlorine peroxide in water as the electrolyte. The E.M.F. assigned to these cells is only approximate, as it was found dependent on the quantity of chlorine peroxide in solution, which was constantly changing. The resistance also varied with the different degrees of concentration of the exciting fluid.

Different forms of amorphous carbon were substituted in place of graphite in the first form of cell. Gas carbon gave an E.M.F. of 0·007 volt when opposed to platinum in sulphuric acid; on the addition of chlorate potassium the E.M.F. rose to 0·5 volt.

Carbon produced by the action of sulphuric acid on cane sugar in this experiment gave an E.M.F. 0·3 volt.

The carbon of animal charcoal, wood charcoal, coke and anthracite gave an E.M.F. variable with each form, ranging from 0·3 volt to 1·25 volt. The measurements of E.M.F. of the various combinations were made with the electrode immersed in separate parts of the same solution, that the concentration of the liquid and quantity of gas in solution might be as nearly equal in each cell as possible. It was found when the carbon in comminuted form was contained in a porous cup that the combination gave an E.M.F. of 1·24 volt, apparently due to the presence of the oxygen of the air.

It is impossible at the present stage of the investigation to assign any definite value of the E.M.F. to these forms of amorphous carbon. In some cases they appear to have an E.M.F. higher than that of graphite.

The energy of the combination of carbon and oxygen when completely oxidised to (CO_2) carbonic acid gas is stated to be 9624

* Great care must be taken in the preparation of this gas, as it explodes at a temperature of about 140 F. It can be preserved in the dark, and is decomposed by sunlight into its component parts.

† This cell has been described in *Proc. Roy. Soc.*, No. 244, 1886; *see* also *The Electrician*, August 6, 1886, p. 264.

Digitized by Google

foot-pounds per grain equivalent, which is 2·0594 equivolts.* In these carbon elements the E.M.F. is not so high, as there must be deducted the counter E.M.F. or polarisation, and the energy due to the force of setting chlorine free.

Analyses prove that ($H_2SO_4 + KClO_3$) sulphuric acid + chlorate of potassium oxidises carbonaceous bodies to CO_2, and, further, that such bodies first are changed to compounds soluble in the acid (caramel-like substances), which are rapidly oxidised to CO_2.

Undoubtedly the direction of experiments in the future will be to find some substance which will absorb oxygen from the air and give it up to the carbon; in fact, acting as a carrier of oxygen, so oxidising it without heat; and this is not improbable, as we already know of substances which do this, though giving a low E.M.F., as, for instance, the ferric salts are reduced to ferrous by agitating their solutions with carbon, being regenerated by absorbing oxygen from the air.

By pursuing this line of investigation we can be sure we are not ignorantly striving against any law of nature when attempting to convert the whole potential energy of carbon into electrical energy.

* See Sprague's "Electricity," p. 519.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *Jan. 7th*, 1888.

A Note in a recent issue of your paper gave an estimate of the number of telephones in use in the United States as 175,000. This, however, is very far below the actual figure. The number of telephones that were in use by the various sub-companies and licensees of the American Bell Telephone Company last week was no fewer than 378,885, making an increase for the year of a little over 25,000, and an increase over 1885 of about 55,000. The largest gain exhibited in the development of the telephone was in 1883, when the gain in a single year was about 60,000 instruments. The fact that the yearly increase now is so steadily large is good evidence that the telephone service, with all its imperfections, is appreciated, and that the rates are not prohibitive, as is so often claimed. It is amusing to see how the anti-telephone agitation breaks out or is fostered first in one place and then in another. The work is generally begun by some enterprising newspaper in search of a sensation, and Chicago has just given us an instance of this kind of work. The *Tribune* there, after a series of articles enlarging in the usual way on the "miserable service," "excessive charges," "unscrupulous greed," &c., proceeded to issue about 500 circulars to representative business people on the subject of telephone rates, asking what they thought about it. A copy of this circular happened, however, to fall into the hands of one of the other papers, which immediately made the campaign its own, sent out its reporters, worked up the interviews, and then rested in the blissful consciousness of having secured a "first-class beat." But while this may be delightful excitement for enterprising newsmen, it is a little annoying to the telephone company.

Some notable efforts are now being made here to utilise water-powers that have been more or less neglected on account of their remoteness from the place at which the power could be utilised. At Sault Ste. Marie the local Edison Company has been getting ready a plant which will utilise 1,800 horse-power, and which, as it has 32,000 square miles of water in Lake Superior to draw on, is not likely to suffer from drought. At St. Catharine's, Ontario, a new electric railroad on the Van Depoele system has gone into highly successful operation with a total equipment of ten motor cars operated by water-power. This road has available nearly 1,200 horse-power from the Welland Canal. At Ansonia, Ct., another Van Depoele electric road is being built, for which the generators are also to be driven by water-power. This road will not only carry passengers, but will also handle heavy freight. Besides these and many other projects of less imposing character there are two really big schemes on foot. One is a Californian project involving nothing less than the utilisation of the water power of the beautiful Lake Tahoe by means of an immense siphon. It is asserted that through the medium of electricity no fewer than 100,000 horse-power could be distributed from this source. Comparing with this idea is that of utilising the enormous power of the Niagara River, and it is understood that Mr. J. F. Kerns, who has an invention for that purpose, has been granted the use of 500ft. of Government frontage of the river to make his experiments. In this case, again, electricity is proposed as the great distributor, and despite the high price of copper it certainly seems to have a better chance than other agencies. Out West, by the way, an extensive use of Sprague motors is to be made in connection with mining operations and utilising water power.

Some light on the rapid development of the Westinghouse Company's alternating system is thrown by a compilation or table of central stations that has just appeared in the New York *Electrical Engineer*. The list comprises no fewer than seventy-two stations, which figure up a total of not less than 124,950 lights. These stations are in all parts of the country, and include such large places as Pittsburgh, Buffalo, New Orleans, Baltimore, Richmond, Minneapolis, Philadelphia, Denver, and Chattanooga.

Your attention has already been drawn to the fight that has been waging in Philadelphia between the city council and the electric light companies. The matter has been of unusual interest, because there has been so freely expressed on the part of many of the leading politicians and others in Philadelphia an intention to take the business away from the electric light companies, and to establish a plant to be operated by the city. As a general rule, propositions of this character are not viewed with much favour in America, and it does not now seem likely that even in Philadelphia the plan will be carried out. For the present there is a compromise, the companies having agreed to continue lighting their respective districts for the next three months at the prices named in their recent bids. It looked at one time as though an absolute deadlock would occur, and as a precautionary measure some of the old gas lamps along the leading thoroughfare, Chestnut-street, were actually refurnished with burners. There is no fear, however, of any definite return of gas, and the electric light system in Philadelphia is practically being extended about as quickly as any one could expect or well desire. In Detroit an attack made on the local Brush Company has virtually failed, the company having just closed a new contract with the city for a term of three years.

Some record was recently made in these notes of the work done here by the Subway Board. It may be added as an interesting comment on the difficulties in the way of moving the innumerable poles which we maintain in our streets as a reminder of the forest primeval which stood there not so long since, that the Board has succeeded in taking down the enormous total of 217 poles, chiefly from streets of which they were the main ornament, streets that by no possible stretch of language or imagination can be described as beautiful, streets to which, in fact, they gave an air of business that was hardly in keeping with the surroundings. It is promised that a great many poles are to fall within the next three months, after which time perhaps the Chinaman will have to find a new place for his advertisements and the Anarchist a new notice board for his inflammatory proclamations. The fact is, the Board is still at the very outset of its work. Over in Brooklyn the Subway Board has succeeded during the last year in removing 17 poles.

The National Electrical Light Association is to hold its next meeting at Pittsburgh, a city which is especially interesting at the present time to electricians, from the fact that it is now the home and head-quarters of the Westinghouse Electric Company. This meeting will take place in February. The summer one will be held, it is said, at Cleveland, the home of the Brush Company, and thus the association will have an opportunity of making an interesting comparison between the latest developments of electrical application and the earlier ones, with which the Brush Company, the pioneer in the field, is associated. One of the leading topics at Pittsburgh will undoubtedly be the alternating system, and probably some

Digitized by Google

very interesting data will be contributed to the discussion by those who have been operating alternating current plants during the past year.

The latest addition to the list of "cable knights" is noted here with much interest. The recognition thus bestowed on the work and position of Sir John Pender is seen with pleasure, even by those who attach no importance to titles and by those who are in the opposition. I imagine that Sir John was the recipient of many despatches of congratulation from this side. It is thought, however, that while the powers that be were about it they might have conferred an honour adequate to the prominence of the man and the vastness of the interests he represents. We see not a few Colonial notables here, and it seems as though every minor functionary ruling over the destinies of some granite chip of an island gets the order of K.C.M G. If suggestions as to these matters may fitly come from Republican America, why does not Her Majesty create an order for rewarding distinguished services in the arts and sciences? Why should such men as Sir John Pender be lumped in with the Deputy-Lieutenant-Governor of Borioboolagha and the ex-Assistant Commissioner of Excise of Assamtee?

CORRESPONDENCE.

THE EMPLOYMENT OF PERMANENT MAGNETS FOR SIPHON RECORDERS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In *The Electrician* of the 11th Nov. I notice a description of a permanent magnet recorder, exhibited by the Commercial Cable Company at the Electrical Exhibition in New York, and said to be the invention of Mr. Charles Cuttriss, that company's electrician. Will you kindly allow me space to say that as far back as October, 1882, I had a circular magneto recorder, identical in all essential points with the one described, working on one of the Anglo-American Company's cables at this station, and I soon afterwards submitted specimens of the signals received from Valentia, on that instrument, to Sir William Thomson.

The original drawings of the circular magnet which were made by me in 1881 can no doubt be seen at the works of Messrs. Paterson and Cooper, late of Little Britain, which firm made and delivered to me that form of magnet in July, 1882.

I believe that this form of siphon recorders are now made by Messrs. Elliott Brothers for some time past.

In April, 1885, my patent vibrator was placed on the recorder at this station, and has ever since worked well when required, and has proved a most useful adjunct to the recorder. I think, therefore, I may justly claim priority of the invention as far as Mr. Cuttriss is concerned, both for circular magneto recorder and vibrator.—Yours, &c.,

William Dickenson.

Anglo-American Telegraph Company's Station,
Heart's Content, Dec. 30th, 1887.

SIR WILLIAM THOMSON'S PAPER "ON THE APPLICATION OF THE DECI-AMPERE OR CENTI-AMPERE BALANCE TO THE DETERMINATION OF ELECTROMOTIVE FORCES OF VOLTAIC CELLS."

A Correction.

Sir W. Thomson will feel obliged if the Editor of *The Electrician* would kindly note in an early issue the enclosed correction.

The University, Glasgow, 17th January, 1888.

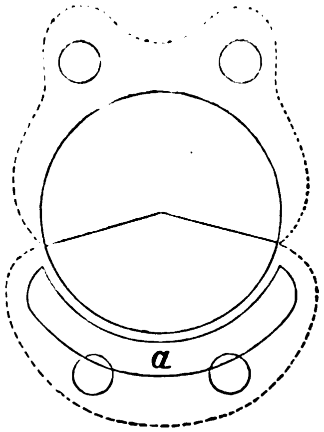
On account of the numerical error in this paper (see *Electrician* for December 16, 1887), pointed out by Mr. Desmond FitzGerald in a communication to a contemporary journal on January 6, 1888, referring to Mr. Gray's measurement of November of the electromotive force of Clark cells, constructed by Mr. Bottomley last March, substitute for the last four lines of the article the following:—"Correcting to 15deg. C. we obtain 1·4346 Rayleigh volts at that temperature. This result is interesting as showing a difference of less than $\frac{1}{10}$ per cent. from that obtained by Lord Rayleigh for similar cells, which was 1·435 at 15deg. C."

THE BALL UNIPOLAR DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of Dec. 9th, in a Note on the sparking of brushes, page 96, you make this remark in relation to the Ball unipolar dynamo:—"Of course we all know, on the other hand, that this machine never could, and never would, work according to any recognised theoretical assumptions."

As I at one time made a number of measurements and tests of Ball machines, when in charge of the electrical engineering department of the Cornell University, I shall have to differ with you in regard to that statement. The Ball machine not only can, but *does* work exactly as theory would indicate. Referring to the rough sketch which I enclose, the lines of magnetic force leaving the pole-piece *a*, and entering the core of the armature, must leave



it somewhere, and in the absence of the pole-piece on the opposite side, they leave it by the best and easiest path to be found. They go partly through the air across to the pole-piece of the opposite armature perhaps, but mainly to the two field cores which pass across over the armature, and so return to the first pole-piece through the mass of iron which makes up the field-magnets. The absence of the pole-piece over the armature simply causes a greater resistance in the magnetic circuit than would otherwise occur, less of the lines of force on the whole pass through the armature than would pass though it if both pole-pieces were used, and those which do pass through it pass out with more or less irregularity. They are concentrated under the round bars forming the field, and therefore develop a greater electromotive force in the coils of wire passing those two points, causing a certain amount of irregularity in the action of the different coils, and, therefore, very serious sparking at the brushes upon the commutator. By taking out the upper field magnet bars and turning them end for end, so that the pole-piece over the second armature was transferred to the first, bringing the one armature between the two pole-pieces, as in the ordinary Gramme machine, the number of lines of force passing through that armature, as indicated by the electromotive force developed, was nearly doubled. That is, the one armature alone gave, when between the two pole-pieces, almost the same electromotive force as the two armatures when acted upon each by its own pole-piece. An exploration of the magnetic field, by means of a special coil put upon the armature for that purpose, which gave the intensity of the magnetic field at each point in the circumference around the armature, showed a very strongly marked increase in the magnetic intensity under the bars on top of the armature

Digitized by Google

where the pole-piece was absent, and showed also that the electromotive force of one polarity existed through less than 180° on the side that was acted upon by the pole-piece, and that the opposite polarity existed through something more than 180° on the other side, as shown roughly in the diagram which I send, where the dotted line is a rough indication of the strength of the field at different points when the armature itself was producing no current. The sketch is drawn from memory, and is only intended to show in a rough way what the condition of things was.

A great deal has been said about this Ball machine, but I have not seen anything in it that is strange or unaccountable. The only thing surprising about it is the fact that so great an output is obtained from these machines for so small a weight. This is largely due to the fact that comparatively fine wires are used, which make the internal resistance of the machine rather high, and therefore reduce somewhat the efficiency. The machine is, however, fairly efficient, and so far as the efficiency of conversion is concerned is equal to any of the best machines. In other words, the local action in the machine has been reduced to a very small amount, and the claim which the inventors make is that it is the reduction of the magnetic field by using only one pole-piece over each of the armatures that enables them to obtain so small a degree of local action. They put it in this way, that if they were to put the one armature between the two pole-pieces, thereby nearly doubling the intensity of the field, as was shown by my experiments, the local action in the armature core would be nearly doubled, and they would, therefore, have to run at a much slower speed to prevent heating of the core that would otherwise occur, and therefore they would be unable to obtain from the one armature so great an output as they now do from the two. But this is not a point that I care to discuss. The object of this letter is to point out that the machine works like any other dynamo, differing from them only in the fact that the field is a very irregular and unsymmetrical one, and, therefore, causes a serious sparking at the brushes, which always must result from any such want of symmetry.—Yours, &c., WM. A. ANTHONY,

Electrician to the Mather Electrical Company.

Manchester, Conn., January 5th, 1888.

[We venture to think that Prof. Anthony's remarks as to the output of this machine rather tend to bear out our previous observation; it is at least clear that the mere employment of fine wire in the armature (entailing increased self-induction) cannot possibly increase the output unless the current density is correspondingly increased. On the other hand, it is quite in accordance with the experience of dynamo builders in this country that *in a weaker field* it is possible to employ a higher current density without overheating the armature, and it is obviously not difficult to account for this theoretically.—ED. *E.*]

MR. STANLEY ON THE PHENOMENA OF RETARDATION IN THE INDUCTION COIL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In a paper read recently before the American Institute of Electrical Engineers, by Mr. W. Stanley, jun., attention is called to what I had believed to be an exploded theory. "Phenomena of Retardation in the Induction Coil" is the title of the paper, and the lag of current behind the E.M.F. is explained on the supposition of a magnetic lag in the iron core. Such an apparent ignorance of the elementary principles in so successful an engineer as Mr. Stanley undoubtedly is surprises me greatly. I had thought the experiments of Silvanus Thompson, Mordey, Willoughby Smith and others had settled this point long ago. Without criticising the paper as a whole, I will draw attention to a salient point which should not pass without notice in our scientific journals.

In the curve of E.M.F. of a coreless armature, Mr Stanley says the effect of induction is *not* to cause a lag, but only to lower the value of the E.M.F. at each moment. This, I fancy, will be news to most of your readers.

Mr. Stanley admits that induction causes lag with an iron core. So it would seem that there are two sorts of induction, one of which lowers the value of the impressed E.M.F., whilst the other only tends to delay it.

Mr. Stanley has done too good work to make such statements without due consideration, and I should be glad if you, Sir, can explain the matter.—Yours, &c.,

ALBION T. SNELL.

[We may refer our correspondent to some observations in our editorial columns.—ED. *E.*]

INDIA RUBBER COMPENSATORS FOR OVERHEAD WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was much surprised to find in last week's edition of the *Electrical Review* a Note which refers to the perfect uselessness of my invention, described in your valuable journal of the 6th inst., upon the grounds that "less than a year's exposure to the continual action of wet and dry heat and cold would completely perish the rubber." How is it, then, that the rubber springs on tram cars last on an average for five years exposed to all weathers and rough usage? In order to answer this question to my best ability I am of a belief that india rubber, as long as it is in a state of vibration, will not solidify or become inelastic for some years; but, on the other hand, if allowed to remain exposed and inactive it will soon become hard or perished, because the vibration tends to prevent the molecules from combining to form an inelastic mass.—Yours, &c.,

144, Kennington-road, S.E. R. G. BOZON.

THE SKRIVANOW CELL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I wish to prepare a small cell for an electric star light. Munro and Jamieson, in their pocket book, recommend the Skrivanow cell, but I want some directions how to place the chloride of silver in the cell. Would you, or some of your readers, kindly oblige me?—Yours, &c., P. T. H.

Nystad, Finland.

[We believe that the chloride is made into a paste with a 4 per cent. solution of caustic potash. This is placed round the silver plate, and the whole is wrapped with parchment paper. When the battery is exhausted (*i.e.*, the chloride reduced to spongy metallic silver), the paper is taken off, and the plate dipped in dilute nitro-hydrochloric acid for a time, which re-forms the chloride.—ED. *E.*]

TELEGRAPHIC INVENTIONS AND THEIR INVENTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following list of inventions and their inventors covers a large part of the whole ground of the marvellous march of telegraphic science which our age has witnessed:—The Needle Telegraph, Cooke and Wheatstone; the Morse Alphabet and Printer; the Siemens Printer; the Wheatstone Printer; the Duplex System, Gintle, Siemens, and Stearns; the Quadruplex System, Stearns and Edison; the Multiplex System, Delaney; the Telephone, Bell and others; the Neutralisation of Induction by Crossing the Line Wires, Prof. Hughes.

So far as I am aware this list does not include the names of any who are now or have at any time been employed as telegraphic engineers by the English Post Office. Yet in your recent remarks on the spring shackle invented by Mr. Caws, and on the compensator invented by Mr. Bozon, you argue that such appliances would have been invented by the Post Office engineers had they been really necessary.

I cannot doubt that the Post Office engineers and electricians have rendered most invaluable aid to science by those practical and experimental works for which they possess exceptional

Digitized by Google

facilities; but, judging by the above list, history does not justify us in looking to our public officials, but rather to outsiders, for new ideas.—Yours, &c., G. W. ERRINGTON.

[Mr. Errington appears to overlook the fact that the Post Office officials cannot patent their ideas; if they could his list would be largely increased; and even as it stands, the major portion of the inventions mentioned have become obsolete, at all events in their original form, their adaptation to modern wants being due entirely to Departmental ingenuity.—ED. *E.*]

MEDICAL ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have noticed in your paper of late several communications which are evidently inspired by a person who was in our employment for a few weeks, and who writes these effusions out of pure pique and spite.

We are somewhat surprised that a respectable scientific journal should open its columns to such abuse, which, considering the status we hold both with the public and the profession, is not calculated to do us the least harm.

The signed letter in your issue of the 6th inst. is a pure fabrication from beginning to end; but we do not intend to give this individual a cheap notoriety by an action for libel, in which we should undoubtedly be successful, but should nevertheless be unable to recover even our costs.

Trusting you will give this letter the same publicity that the thinly veiled attacks upon us have obtained.—Yours, &c.,

C. B. HARNESS.

The Medical Battery Company (Limited),
52, Oxford-street, Jan. 12, 1888.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

MR. EDWARD GRAVES' PRESIDENTIAL ADDRESS.

(*Concluded from page 248.*)

The use of the telegraph is not at all in proportion to the population of the various localities it serves. Much depends upon the nature of such populations, on the avocations in which they are mainly engaged, and the extent to which fluctuations are liable to occur in prices of the commodities in which they are interested. A certain constant quantity, as it may be considered, of telegraphic business arises from the needs of domestic life. This is common to all centres, but necessarily varies as the class of the inhabitants varies. From the east of London, for example, 500,000 residents have occasion to communicate by wire on their ordinary affairs much less frequently than a corresponding number of residents in the west. Speaking as a general rule, the operative classes of the community have less widespread interests than those placed higher in the social scale. They receive in relation to their numbers fewer letters per head, and send fewer telegrams. The employment by them of the speediest engine of communication is decidedly on the increase, but it has still great room for growth.

London is far and away the centre of greatest telegraphic activity; but the fact of its being the capital—the seat of the Legislature and of the Law Courts the headquarters of the Stock Exchange, and so on—gives it so many special features, independent of its widespread commercia interests, that it can hardly be properly compared with any provincial town as regards the amount of business done. It may, however, be of some interest if I contrast a few of the leading provincial towns in this respect.

Taking the calculated population within the free town deliveries of letters up to the end of 1886, and the actual number of telegrams originating within the same limits for the year ended September 30th, 1887, the results are as follows:—

	Population.	Telegraph Messages.
Glasgow	740,000	1,444,741
Liverpool	730,000	2,268,062
Manchester	613,982	1,660,538

exclusive in all cases of the messages collected for America and the Eastern Telegraph system, which are despatched by special wires worked by the cable companies. Upon these figures it should be remarked that the population attributed to Glasgow includes the ring of minor boroughs excluded from the city in a municipal sense. In the case of Liverpool all north of the Mersey is reckoned, but Birkenhead, largely peopled by persons interested in Liverpool commerce, is excluded. But the fact remains that the seaport possessing the largest trade of any, out of London, in the kingdom, does the largest telegraphic business. Manchester includes Salford in its number of residents, and, being a central point for numerous surrounding towns who look to it for guidance in commercial matters, ranks considerably above the larger population of Glasgow as regards the employment of the telegraph. Further—

	Population.	Telegraph Messages.
Birmingham	420,000	672,714
Edinburgh (with Leith)	319,030	667,758
Dublin	319,000	582,083
Newcastle-on-Tyne	151,500	546,294
Bristol	227,127	466,412
Hull	186,290	452,921

show the comparative telegraphic pre-eminence of the seaports as compared with the subordinate capitals and the great Midland manufacturing centre. Edinburgh, including Leith in its boundaries, adds thereby a place of material commercial activity to its semi-metropolitan population.

Other cases strengthen the conclusion that the nature of the trade rather than the absolute volume of business must be considered in determining this comparison, thus—

	Population.	Telegraph Messages.
Leeds	296,108	337,998
Belfast	225,000	344,603
Sheffield	305,000	257,056
Nottingham	211,424	236,143
Leicester	127,500	188,890
Cardiff	115,000	394,891
Dundee	152,840	206,168
Aberdeen	113,212	206,680
Newport (Monmouth)	40,000	153,193

For most of these divergencies and discrepancies persons familiar with the characteristics of the various towns will easily find reasons; and I may add a few more instances—

	Population.	Telegraph Messages.
Portsmouth	132,659	154,905
Plymouth (*ex* Devonport)	96,142	185,454
Southampton	61,000	158,069
York	60,500	126,541
West Hartlepool	32,000	114,014
Oxford	44,000	86,524
Chester	40,340	98,721
Bath	57,000	81,126

Analysing the figures given above, we find that Liverpool, with rather more than 3 messages per annum per head, Newcastle-on-Tyne with rather more than 3½ messages per head, Cardiff with somewhat less, Newport (Monmouth) with an approach to 4 messages per head, and West Hartlepool with about 3½ messages per head per annum, rank highest among English towns as contributors to telegraphic employment. It may be remarked that Oldham and Blackburn, both containing over 100,000 of population, do not figure in the list of the 52 towns whence the greatest number of messages are forwarded, although many much smaller places do so.

In some instances apparently extraordinary results are explained by local facts. Thus, the 60,500 residents of York apparently do much more business than the 91,000 inhabitants of Norwich, a city of the same general character (126,000 messages to 89,000); but probably the circumstance that two important race meetings are held at the former place, and that the great railway station there is far more important to the travelling community than any at Norwich, may account for the distinction. If it were possible to analyse the apparent discrepancies between the figures of other towns, no doubt there would be some similar means of explaining them.

This much may serve to illustrate the changes that the electric telegraph has wrought, and the benefits it has conferred.

The operations of the telephone as yet are of a more limited character, but even as at present developed are of little less interest. The telegraph may be regarded, in the main, as the rapid public transmitter of private or public correspondence; the telephone as the instrument of personal, and therefore strictly private, communications between man and man. If the communication is perfect, and so arranged as to be free from interference, not only can the varying sounds of voices be recognised through the connecting wire, but the tones may be distinguished in many cases, and the speakers known. One individual can speak freely to another, obtain his answer, and make any rejoinder he thinks fit. An entire business transaction can be completed without any pre-arrangement, and confidential questions can be equally confidentially replied to. Reis advanced the discovery of the means of transmitting the effects of speech to the verge of success, but did not pass the verge. Bell completed what Reis had begun, and placed a workable instrument at the disposition of the world. Edison and Hughes strengthened the forces employed for the transmission of sound waves, and the telephone (as we know it) was completed. Founded upon the laws that guided the production of the telegraph, the generation of the telephone was especially rapid—but a brief space has elapsed between its inception and its realisation. The marvels it has wrought are less striking than those of the telegraph, but the processes by which they are produced appear more marvellous still. At present the operation of wide-stretching patents perhaps cramps, to some extent, the improvement of the mechanical apparatus needed for telephonic expression, and time has not sufficed to admit of all difficulties in the way of its extended use being overcome; but seeing how few years have elapsed since the discovery of the thing itself, we may reasonably hope for its much greater development in the near future.

Digitized by Google

EMPLOYMENT ARISING OUT OF THE VARIED USES OF ELECTRICITY.

There are many indirect methods in which labour is employed, because electricity has been utilised, that do not admit of being ranked under any special head of its operations. Wire drawers, and, in consequence, iron works, and copper smelting works, also copper plate rollers, are largely engaged in the production of materials for the transmission of electric signals. Timber dealers and their workmen, creosoters, insulator makers and their *employés*, brass workers, spelter makers, engine builders, boiler makers, glass blowers, carbon plate and rod manufacturers, and very numerous other occupations, receive considerable employment by means of the demands that electricity has encouraged; but as the firms engaged do not generally devote themselves solely to meeting such demands, but exist also for wholly distinct purposes, it is impossible to arrive at any idea of the amount of labour on electrical account that they employ. It is equally impossible to enumerate all the persons engaged in absolutely electrical trades. In Sheffield there are 172 electro-plating and electro-gilding manufacturers, employing in all about 5,000 hands; and in Birmingham there are 99 manufacturers of the same class, two of whom employ 300 persons each, and others a large, though uncertain, number in the aggregate—one thing is certain, it must in the total be very large.

The electroplaters, electrotypers, and the like are so widely spread that it is impossible to collect reliable figures for them—the instances preceding must suffice; a similar conclusion to the former is only possible. It is the more difficult to arrive at any satisfactory determination because it is simply impossible to ascertain how many persons were employed in dealing with the old methods of working in these directions.

In London alone there are, according to the "Post Office Directory" of 1888, 535 commercial firms, of greater or less magnitude, engaged in various operations of which electricity is the main spring. Some of these firms appear under several trade descriptions, and it is impracticable to assign any reliable figures to the number of their *employés*, but in the total it must be very considerable. Each employer, although carrying on probably several distinct branches of trade, must engage the full time of various persons, in most cases, in each distinct branch. To the London employers must be added the numerous others existing in our provincial towns. I have, however, obtained reliable figures wherever possible.

I will first take the case of the British Inland Telegraphs.

The English Post Office employs solely in the conduct of telegraphic operations 18,303 persons. These individuals give *all* their time to work in connection with the electric telegraphs; many thousands of others are partially employed in the same work, but they discharge other duties also, and possibly would be required for those duties did not the telegraph exist. I have therefore not included them as among those who have found their means of subsistence through the operations of electricity.

To this ascertained number must be added those who are employed by the various railway companies, either in the conduct of their general telegraphic business between station and station, in special duties in connection with the signalling of trains, or in upholding the telegraph lines existing on the different railways. I could not, in the time available, get the figures I wanted from every railway company. I therefore contented myself with those of four great companies, whose entire systems extend over a length of 5,881 miles. I found that they employed 1,627 persons solely on telegraph work, and, as the entire mileage of railways existing in 1887, as given in "Bradshaw's" handbook, was 19,339 miles, I apply the rule of proportion, with the result that I find the total number of railway servants wholly engaged in electrical work to be 5,383. Many of the railways which go to make up the gross total mileage are small concerns, many are large ones; but as the infinite subdivision of lines multiplies the number of persons employed in carrying out the operations of any branch of work, I do not think that I can be far wrong in applying the ascertained results of the figures I have reliably obtained to the average of the whole railway system.

But, like the Post Office, the railway companies have a very great number of persons partially though not wholly engaged in similar operations. The men at the numerous signal cabins not only work the levers controlling the fixed signals, but usually manipulate the block telegraph besides. At many small stations, where there is but a limited force engaged for the discharge of all duties, the booking clerk works the instrument in addition to his other employments. I do not count either of these classes among the purely electrical *employés*.

The Exchange Telegraph Company, a licensee of the Post Office, engaged mainly in the supply of intelligence of special events to clubs, public institutions, and private persons, employs the entire time of 182 persons, besides the partial time of many others who supply the company with reports and information.

Thus the number of individuals engaged entirely in the transmission of business brought about by the existence of the electric telegraph in Great Britain and Ireland is, as nearly as I can ascertain, 23,868 persons; to which must be added an army of persons who probably find their incomes more or less considerably increased by the same cause, though not entirely dependent upon it.

I intended to confine myself to the economical figures of the British Islands only, but I may remark that if the rule of proportion holds good in this branch of the subject, and the entire mileage of public telegraph wires of all kinds in this country be, as is the case, 229,000 miles or thereabouts, while those of the world approximately amount to 1,800,000—omitting submarine cable—we have, as in the one case 23,868 persons are employed, a total number of 179,748 persons who find a field of labour in the working of telegraphic communication throughout the globe. It is impossible, seeing the varied circumstances existing in different countries—in some there are long mileages of wire connecting comparatively few offices or stations, in others there are short mileages connecting many stations—to say that this total is correctly arrived at, but it cannot fail to be at least an approximation to the truth. In some countries the available figures are indefinite as regards the differences between Governmental lines and wires for railway purposes; in some, telephone lines are mixed up with the figures for telegraph lines. Thus the totals I have given are liable to error, but it is, at any rate, error on the right side, and the number of individuals engaged in their working in all probability will rather exceed than fall short of the numbers I have given. The facts as to the partial employment of individuals not enumerated as telegraphic *employés* is common to all the world, and not by any means limited to the United Kingdom. To the known and fully occupied a very large addition must be made to represent the unknown and partially occupied.

The Submarine Telegraph Cable Companies must next be considered. From three of these—the Eastern, the Anglo-American, and the Submarine—I have obtained the actual figures. Their *employés* number in all 2,168. These three companies possess about 36,697 miles of wire, and throughout the globe there are about 107,000 miles of cabled wire. Deducting those cables that are really integral portions of land circuits and which have no separate organisation, the persons employed in working them are treated as if engaged on land telegraphs. By proportion, this total mileage of wire in cables should make the entire number of persons employed 6,315. Some time ago the Eastern Telegraph Company endeavoured to get up a census of the number of persons employed in submarine working throughout the world, and arrived at a total of 4,844 persons; but I am not certain that all the lines included in the above calculation were existing at the time such census was compiled. I am pretty sure they were not. I take the actual total of persons employed at 6,000.

These cable companies employ also cable ships in repairing and maintaining the submarine lines. Of these I speak more fully when dealing with cable manufacturing companies.

Next in order come the Telephone Companies. These, in proportion to the number of their wires, of course employ comparatively few persons, as the renters of the lines are their own manipulators; they employ attendants only at exchange switches; but, nevertheless, the information received from all the companies existing in Great Britain and the North of Ireland shows that their operations give employment to 2,386 persons. To this number must be added that of the company working in Dublin and the South of Ireland; thus the total is raised to certainly 2,500 individuals, probably more. I have no facts upon which I can extend the comparison to the world generally, but, seeing the universal adoption of this means of communication, and the extent of its development in the United States especially, there can be little doubt that the aggregate total of persons engaged in carrying out this form of electrical undertaking must at least reach 30,000.

The electric lighting industry then comes under consideration. From five of the largest concerns engaged in the business of either providing apparatus and mechanism for its production, or utilising such means for the actual installation of the illuminant, I have received returns of the average number of their *employés*. These amount to 1,828. The five concerns I applied to, although among the largest, by no means represent the greatest part of the entire industrial army occupied in the like pursuits. I believe that there need be no hesitation in putting down at least 5,000 as the total for our country; and, keeping in mind the fact that all countries welcome and adopt the new light—some to an extent much exceeding our own—it is reasonably certain that twenty times this number, or 100,000, will not be too great a figure to represent the entire strength of the workers in this field. Along with the electric light companies and the employment they give, I comprise those of the makers and producers of secondary batteries or accumulators mainly occupied in operations auxiliary to the production of electric light.

There remains to be considered the number of persons employed by the submarine cable and insulated wire manufacturing companies, who most of them make also various instruments used in telegraph working, and in other electrical applications. The extent of the employment given by them varies considerably, as, of course, cable making is a somewhat fitful industry—the periods of active construction and of comparative slackness alternate with each other. From the three largest companies on the Thames, I learn that the average number of persons employed by them varies from 5,457 at a busy time to 1,803 at a dull one. This gives an average of 3,630. The trade, so to speak, is more concentrated than in the case of the electric light, and it is probable that about 5,000 persons will be a fair allowance for the entire number engaged in it in these realms.

In the foregoing totals are included the number of persons habitually employed on the cable-laying ships of the various manufacturing companies, as is also the case with the repairing ships belonging to the different cable companies. The vessels represent a kind of international fleet engaged solely in attendance upon the cables in which their owners are interested. They are of all sizes, from the gigantic "Silvertown," "Faraday," and "Scotia," to vessels of 300 tons and 400 tons burden. Our mercantile marine, therefore, must be counted among the occupations benefited by the advent of electricity.

We must not overlook the large body of persons engaged in teaching the aspirants to electrical knowledge. At universities, colleges, and technical schools a new branch of science has been added to the previous curriculum. Professors, demonstrators, and their assistants represent in the whole a very important and numerous class. Their pupils, in an appreciable measure, represent workers ranked in one or other of the occupations I have mentioned, while numerous others have as yet attached themselves to no special field of work, but are preparing to take part in some definite sphere of labour when their studies are sufficiently advanced. It is amongst these regularly trained for the conflict that we must look for our future victories over the inert forces of nature. It is they who will advance that which as yet is struggling with the difficulties that surround the unknown. It is to them that we must look for future discoveries

Digitized by Google

which will make that plain and easy which now has to be sought for through much trial and many errors. In the early days men groped in the dark towards the light, as it were; but our present students of electricity have at their disposal a clear *résumé* of all the achievements of the past to aid them as a torch on their way to fresh operations in the same field.

Finally must be mentioned the technical press. Independently of the papers devoted mainly to other interests, such as the *Engineer*, *Engineering*, and their like, which give large space to electrical subjects, we have in England, America, France, and Germany alone between twenty and thirty organs interested wholly or specially in the publication of facts or opinions concerning the operations of electricity. This department of the press is invaluable in rapidly spreading a knowledge of what is doing by various workers in the electrical field throughout the globe, and is itself a literary outgowth of the marvellous agent we are regarding.

Considering the foregoing figures, the results come out as follows:—

Employed in connection with	Number of Persons.		Probable No. of Persons employed throughout the world.
British land telegraphs	23,868	....	180,000
Submarine cable companies (mainly British) ...	6,000	....	—
Telephone companies	2,500	....	30,000
Electric lighting	5,000	....	100,000
Cable-making and allied businesses	5,000	....	—
	42,368		

Add to these the individuals that cannot be classified, who must amount in the aggregate to at least an equal number, we arrive at a total approaching 100,000, in round numbers, of persons dependent for their employment on the various operations directly connected with electricity in these islands alone, besides a very large addition to the output of various trades, caused by its consumption of the materials they produce. The employment of 100,000 persons means the support of at least 300,000 of the community. An unusually large proportion of young, or at least unmarried, people of both sexes minister to the calls of electrical work, and hence I take the average family at three instead of the usual calculation of four and a-half or five.

If these figures represent even an approach to the truth, it is evident that throughout the earth there must be 5,000,000 of people at least who would have to seek for other means of subsistence if electricity and its commercial applications had not been made known to man. Thus it is evident that a double blessing has been conferred by the discovery of its potent force—a blessing to the inhabitants of the world at large, who profit by its operations, and a further blessing to the toiling myriads whose field of labour lies in carrying them out. How great will be the numbers similarly occupied and similarly dependent when a century more has rolled away!

Thus far I have sought to sketch, although briefly and imperfectly, the various modes in which electricity is utilised, and to arrive at some idea of the extent of employment derived by the workers who strive to secure such utilisation. But this is at best an approximation to the truth at the present moment. It is little more than fifty years since the powers of the new agent were first turned to practical account, and since that time the record has been one of continuous and unabated progress. Discovery has succeeded discovery, and invention has followed upon invention. At present many fields are entered upon but scarcely trodden. Electro-motors and their like have clearly an unknown, an immeasurable field before them. What is done is as nothing to what will be done. The fusion of the influences of sound and light, the laws of heat in relation to the power we are considering, and its equally important bearing upon those of acoustics, open up so many directions in which we may look for future researches to make much that now shows, as it were, through a glass darkly, clear and distinct, if not to ourselves, at least to future generations. The Leyden jar and the frictional machine taught us the true resemblance between the force they made manifest and the awe-striking lightning discharge from the clouds. Later, more tractable and more easily controlled manifestations of the same agent have been discovered, but in their obedience to control they enlarge greatly the sphere of its uses.

As a stander-by, watching the progress that has been made, and is still making, by the earnest workers who have given to the world so much—marking the difference between the knowledge of the present day contrasted with that which existed over thirty-six years ago, when I first knew the difference between a battery and an insulator, and conceived some vague idea of their respective functions—I am struck with astonishment. In 1852 the Rubicon had been crossed, the theorist had given place to the practical worker, but as yet the latter had not advanced very far from the lines laid down by his predecessors; the spirit of the originators was as yet the controlling influence, but the mind of the student was set free, and each month showed the results of unshackled inquiry. Now fields, undreamed of then, have been opened; new applications have been discovered by which the powers of electricity have been utilised; known applications have been greatly advanced and extended. In the time of which I speak comparatively few of the *employés* in telegraph working—and that, was speaking broadly, the sole demonstration of electricity that could be commercially cultivated—were attracted thereto by any knowledge of the science upon which it was founded, or interested in the progress it might make; most looked to it as something in the operations of which they could contribute with profit to themselves, remaining ignorant of the laws that governed it, or the reasons why certain apparatus was employed to produce its effects. To them any knowledge they might glean was empirical, the pure result of experience in a contracted form. At the present day an entire change has taken place. Into none of the advanced operations of electricity does a youth engage himself without having some taste or liking for investigation and the acquisition of real knowledge of the subject in which he is interested. Societies such as this best justify their existence in lending aid to those who seek to elevate themselves and to know what can be learned from their predecessors in kindred labours.

A distinguished scientific statesman once described the mere *workers* of electric telegraph machines as "ambidextrous monkeys"—they knew only that moving a certain handle to the right or to the left, or a key up and down, produced signals or marks that were legible at the further end of a wire; but how they produced them or *why*, they were supremely ignorant. It is not so with the student of modern days. The man who devotes his life to the electric light, motive power, or other allied branches, knows that he must prepare himself by a careful course of theoretical study before he undertakes practical work. He must know the reasons for all that he does.

Thus, it is clear to me that in the facts detailed lies the strongest justification for the proposed alteration in the name of our society. In the summary of electrical operations which I have put before you I have given the largest space to the electric telegraph and its results. I am justified in so doing, because the telegraph is the most nearly completed of all the branches into which the laws of electricity are directed. No doubt there is still room to improve its processes, but its pioneer work is done, and it is scarcely possible that the future can yield more than progress, however important, in details. When the society was first founded, "Telegraph Engineers" was a fitting name, as it was only in telegraph engineering that any considerable number of the followers of the science we are considering were actively engaged. A great change has taken place; positively even more important than it was then, it is now relatively less so. The field has been so carefully reaped that it offers little temptation to the average gleaner. Speaking generally, men's thoughts are directed to other channels, where they may seek, in partially explored or unknown regions, the fame and profit that may accrue to those who win victories therein. "Telegraph Engineers" are still the most numerous units in our body, but from the force of circumstances they can no longer be said to be the special representatives of its character. The Institution of "Electrical Engineers" is a title comprehensive enough to include all devotees of the science; no class of workers is singled out for undue prominence, no class is by implication excluded.

The President of the Royal Society, in his recent address, told the members of that learned body that the world wanted a great discovery—that it was most desirable that the nature of electricity should be made known and defined. We may be on the eve of such a discovery, we may be far from it. The problem to be solved—that of the true character of the mysterious agent that seems to pervade all nature—ranks apparently with the equally puzzling one, "What is the soul?" Philosophical and theological students have quarrelled over the latter question for many generations without advancing nearer to a solution. Let us trust that "What is electricity?" may, in the fulness of time, receive an answer which will extend the boundaries of its use to purposes as yet undreamed of, and that the benefits it confers on man may be thereby multiplied many fold.

CITY NOTES, &c.

West India and Panama Telegraph Company.—The estimated traffic receipts of this company for the half month ended the 15th January are £2,509, as compared with £2,976 in the corresponding period of 1887.

COMPANIES' MEETINGS.

Eastern Telegraph Company (Limited).

The thirty-first half-yearly ordinary general meeting of the Eastern Telegraph Company was held on Thursday, at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G.

The Secretary (Mr. Geo. Draper) read the notice convening the meeting, and the report of the Directors was taken as read.

The Chairman said that the revenue for the half year ended September, 1887, had amounted to £291,265, or £964 less than for the corresponding period of 1886. The Directors, however, considered that satisfactory, because the larger decrease of revenue caused by the reduction of tariff to India was sensibly diminished, and, indeed, the improvement of traffic with Australia, China, and other countries in the Far East had more than recouped the loss on Indian messages. Their traffic with Egypt, on the other hand, showed a further falling off; but that had been made good by the increase of messages exchanged with Portugal and South America. Having so many points for the interchange of traffic, they found that the loss sustained in one direction was sometimes made up by gain in other directions. For the current half year their prospects were most favourable. Their traffic now showed a small increase every month, and it was hoped that next July, when they presented their accounts for the financial year to March 31, they would be able to give the shareholders a bonus in addition to the 5 per cent. dividend. The total working expenses had amounted to £79,936, or £1,095 less. The general expenses in London had been £8,012, being £48 more. The working expenses at the stations had been £56,386, showing a decrease of £1,743. The principal reduction, however, was in repairs and renewals of cables, which had amounted in the past half year to £34,102, or £19,863 less. Therefore, after charging all expenses, including income-tax, providing for interest on debentures, debenture stock, and preference shares, they had been able to pay an interim dividend on the ordinary shares of 5 per cent. per annum, and to carry forward to next half-year a balance of £29,397, or £16,306 more than in the same period of 1886. The loss of income which had been forced on them at the Berlin Conference, as he had stated at the last meeting, caused for a time a suspension of their bonus, but as he had just said, they were carrying forward a very considerable sum. Until, however, they had closed the year there was always the uncertainty that what might be a large sum to carry forward might be materially reduced by interruptions to the cables. He hoped that as they improved more or less the quality of the cables they put into the sea they would lessen the repairs. He referred also to the Tangiers cable, which had been very advantageous to the trade of Morocco, and had also helped the Company materially. With regard to their wire through France, they had not yet obtained permission from the French Government to extend the time for it; but they had made themselves thoroughly independent by laying a fresh cable from Porthcurnow to Lisbon, Gibraltar, Malta, and Zante. That cable was working most satisfactorily, aiding them in carrying their traffic and placing them in a perfectly independent position if war broke out on the Continent to-morrow. Their system was almost entirely duplicated. Had they depended on one wire, with the interruptions that constantly took place it would have been most unsatisfactory in every sense, as it would have interfered with the dividends and with the telegraphing public, and it would have thrown discredit on the whole telegraphic system. They had entirely got the better of that state of things, as he had said, by duplicating, and, in some cases, triplicating their system. He was glad to say that trade was improving with the Colonies. He hoped that all that they had heard about the gold discoveries in Africa would prove correct. The estimation in which this Company was held by the commercial mind of London was shown by the exchange of their 5 per cent. debentures for 4 per cent. stock, showing that a 4 per cent. stock of the Company was considered a sound investment in the city. By means of their reserve fund they had kept down their capital. They had applied the reserve fund in a good many instances to give security to their dividend. If they had kept their reserve fund intact and laid their new cables out of capital they would have added close upon half a million to their capital. Instead of that course, however, which was open to many objections, they had drawn from the reserve fund from time to time and from their current income, and had partly carried out the duplication and triplication of their system in that way. He thought he might congratulate them on the prosperous condition of the Company at the present moment—prosperous because it was built on a sound foundation. He concluded by moving "That the report and accounts of the Directors to the 30th September, 1887, submitted to this meeting be and the same are hereby received and adopted."

The Vice-Chairman (the Marquis of Tweeddale) seconded the motion.

Mr. L. Nicholson asked whether there was a prospect of the cable being duplicated to the Philippines? He desired to propose a rider to the motion moved by the Chairman as follows:—"That the shareholders of the Eastern Telegraph Company tender to Sir John Pender, K.C.M.G., their cordial congratulations on the recent honours conferred on him by Her Majesty as some recognition of his services to Imperial and Colonial interests." He was convinced that the rider would meet with the warm approval of every gentleman present [cheers]. He referred to the many services which the Chairman had rendered to the world in connection with telegraphy, which had done so much to bring the mother country into communication with her Colonies, and, in fact, the whole of the world.

Dr. Waller seconded the rider, which was carried with enthusiasm.

The motion with this addition was then agreed to unanimously.

The Chairman cordially acknowledged the kind remarks of the share-

Digitized by Google

holders, and assured them that he very highly appreciated what had been said. Submarine telegraphy was his hobby, and it would probably be so during the whole of his lifetime, and he would use his utmost endeavours to promote the welfare of the Company and the interests of the shareholders. In reply to the question by Mr. Nicholson he said that the Eastern Extension Company, of which he was also Chairman, was now in negotiation with the Spanish Government on the matter.

The retiring Directors, Sir John Pender and the Marquis of Tweeddale, were unanimously re-elected, as were also the auditors.

Mr. JOHN NEWTON then proposed a vote of thanks to the Chairman, and said he desired cordially to acquiesce in the congratulatory remarks which had been made. He pointed out that telegraphy had done more than anything else to promote and make federation possible. It was remarkable that telegraphy was not represented in the House of Lords by anyone who sat there in virtue of his connection with the cable system connecting all parts of the world with this country. He hoped the present recognition of Sir John Pender's services was merely an instalment of higher honours to follow.

The motion having been seconded was carried unanimously.

The CHAIRMAN, in reply, said that the resolution was peculiarly gratifying to him and the Directors, because no man watched more closely or critically the working of the Company than Mr. Newton.

The proceedings then terminated.

THE ELECTRO-HARMONIC SOCIETY.

SMOKING CONCERT.

FRIDAY, JANUARY 27TH, 1888.

At the ST. JAMES'S HALL RESTAURANT (BANQUET ROOM), at EIGHT o'clock.

ARTISTES—Mr. Walter Coward, Mr. Arthur Thompson, Mr. James Kift, Mr. Musgrove Tufnail.

SOLO VIOLONCELLO—Mr. W. C. Hann.

SOLO PIANOFORTE AND ACCOMPANIST—Mr. Alfred Izard.

MUSICAL DIRECTORS—Mr. T. E. Gatehouse and Mr. Arthur Thompson.

PART I.

Madrigal—"Down in a Flow'ry Vale" (Festa).
Old English Song—"Once I Loved a Maiden Fair" (temp. James I.), Mr. Arthur Thompson.
Solo Violoncello—"Caprice Hongroise" (Dunkler), Mr. W. C. Hann.
Song—"The Toreador's Song, from Carmen" (Bizet), Mr. Musgrove Tufnail.
Song—"Phyllis is my Only Joy" (Hobbs), Mr. Walter Coward.
Solo Pianoforte—Mr. Alfred Izard. Humorous Song—Mr. Kift.

PART II.

Part Song—"Forget me not" (Abt).
Solo Violoncello—"Czardas" (Fischer), Mr. W. C. Hann.
Ballad—"Oft in the Stilly Night" (Moore), Mr. Arthur Thompson.
Scena—"Travellers All" (Balfe), Mr. Musgrove Tufnail.
Song—"I'll Sing the Songs of Araby" (Clay), Mr. Walter Coward.
Humorous Song—Mr. Kift. Part Song—"Good Night, Beloved" (Hatton).

F. GEERE HOWARD,

Electrical Engineer and Contractor for Wire Running of Every Description.

MANUFACTURER OF WOOD CASINGS

FOR ELECTRIC LIGHT CABLES AND WIRES OF ALL SIZES:
Plain or Moulded, in every description of Wood.

CLEATS, SWITCH BOARDS, SWITCHES, CUT OUTS, &c.,

And every description of Woodwork for Electricians.

Price Lists and Quotations upon Application.

CLEVELAND WORKS, CLEVELAND ST., LONDON, W.

CARBONS.

THE BARNSLEY CARBON CO.,

Manufacturers of

PURE CARBON POINTS, TUBES, FILTERS, CELLS, AND BATTERY PLATES

Of every description.

WORKS: BARNSLEY.

London Agency and Stores: THE GLOBE ELECTRICAL & ENGINEERING CO., 7, Carteret-street, Broadway, Westminster.

TELEGRAPHIC ADDRESS: "CARBON, BARNSLEY."

INSTRUCTIONS FOR THE LAYING AND JOINTING OF UNDERGROUND ELECTRIC CABLES. Profusely Illustrated. Translated from the French of Dr. FRANCOIS BOREL. Post free.

Published by

THE KINETIC ENGINEERING COMPANY, 117, Queen Victoria Street, London, E.C.

MIDLAND ELECTRIC WIRE CO., LEICESTER.

Coverers of every description of Electrical Wire.

FREDK. LACK and SON,

90, STRAND,

CONTRACTORS FOR SHIPS' LINEN & BEDDING.

ALSO FOR

Household and Cabin Furniture, Carpets, Linoleum, China, Cutlery, and Plate for Export.

TELEGRAPH STATIONS FURNISHED THROUGHOUT.

Contractors to the Telegraph Construction and Maintenance Company, Eastern, Eastern Extension, Brazilian, and African Direct Telegraph Companies.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 506.—Vol. XX. FRIDAY, JANUARY 27, 1888. Price 4d.

NOTES.

No one will be surprised at the announcement made by the Chairman of the Direct United States Cable Company at its general meeting last Friday with reference to the languid growth of traffic under the sixpence-a-word rate between this country and America. That rate has now prevailed for nearly two years, and has certainly had as fair a trial as it can have with several superfluous cables competing for the business. Whether it would pay if the cables did not exceed the requirements of the traffic is a question now hardly worth discussing. The interesting and instructive fact which this experiment has demonstrated is that the first rush of business under a greatly reduced tariff very soon ceases to grow. Its progress at first promises to pay in the long-run, but the advance it makes soon becomes less and less, with the inevitable result that the longer it runs the less profitable it becomes, the expenses augmenting faster than the receipts. A speedy return by all the Atlantic Companies to a shilling rate—which would be neither unpopular nor unprofitable—is greatly to be desired.

Last week we expressed some degree of scepticism in this column as to the alleged cases of "sunstroke" caused by the electric furnaces at the Creuzot Works, on the ground that such an effect, if possible, would most likely have been heard of before now. We have since learned on unimpeachable authority that the unpleasant phenomena of facial discoloration, and a shredding of the epidermis, as a result of exposure to the electric arc, has not been unknown in this country. We are glad of the opportunity of extending our knowledge of electro-pathology—if that is a correct expression—but we most sincerely regret that the editor of a valued contemporary should himself have been a victim of so unpleasant an accident. Fortunately, however, the effects are merely of a temporary character.

Three years ago last May Her Majesty's Letters Patent were granted for an "invention" of a surprisingly novel and ingenious character. The specification contains only one claim, which reads as follows, "Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is combining with an article of furniture a primary battery or secondary battery substantially as described." Our reason for giving prominence to this remarkable invention arises from the fact that a circular letter has come into our hands, from which it appears that the inventor has reason to believe that certain person or persons (unnamed) have defrauded him of his just rights, and have made and sold articles of furniture combined with primary or secondary batteries substantially as described without having obtained from him, the aforesaid first and true inventor thereof, a licence so to do. We trust that the publicity which we now give to these proceedings will be sufficient to deter such persons from further carrying on malpractices of so palpable and reprehensible a character. We may add that merely in order to satisfy our own curiosity we should be interested to hear from any of our readers who may happen to have seen such a combination in use prior to the fifth day of May, 1884.

Amongst those who are working at the heat conversion problem in America, some attention has lately been given to a device by Mr. Acheson (of Pittsburg), who has designed an apparatus, which he terms a "cal electric generator." No numerical details of the results obtained have yet been published, and it remains to be seen whether the method adopted is capable of leading to results of practical importance, or whether, indeed, the whole idea is not based upon a mistaken induction. Our readers will, however, be able to form their own views on this point, and we do not wish at present to express a decided opinion. Mr. Acheson's apparatus may be described as a hollow cylinder of iron, through which two coils of wire are threaded. One coil is of fine wire, and is wound closely upon the iron; the second, which is of stouter wire, passes loosely through the centre of the cylinder and extends for some distance beyond. It will be seen that this is nothing more than a transformer with a wide and loose secondary coil. It is not, therefore, surprising to learn that when an intermittent current is passed through the primary coil a current is generated in the secondary. So far, all is plain sailing; but Mr. Acheson now takes the loose exterior wires of the secondary coil, and places them over a row of gas jets, so as to establish a "flow of heat" in the wire. It might have been supposed that the chief effect of this procedure would have been the increase of resistance of the secondary circuit by the rise of temperature; but we are told that, as a matter of fact, the result is to produce a conversion of heat into electrical energy, on a scale sufficiently marked, we presume, to justify the title of "cal-electric generator."

It must be admitted that there is enough in this description to justify some degree of scepticism as to whether the appa-

Digitized by Google

ratus does really effect the conversion of heat, or whether the E.M.F. is not wholly due to ordinary induction. But it is difficult to suppose that Mr. ACHESON can have committed so glaring a mistake as this would involve. And, indeed, from a later communication to the *Electrical World* we learn the fundamental idea which he has had in view. He says: "While I believe that it is to the first publisher of a discovery that the honour belongs, and without any desire to detract from the honour due to MM. HINGHAUSEN and NERUST, I wish, in justice to myself and as a means of establishing the links of the chain, to state that in the month of July, 1886, I made similar experiments to theirs and with like results. It may be that they did their work prior to this date, although the first notice I find of it is in the London *Electrician* of Feb. 18th, 1887."

IN case any of our readers should have overlooked this experiment (which is of considerable theoretical interest) we may here repeat in brief the description which will be found at greater length in our issue noted above. MM. HINGHAUSEN and NERUST placed a thin strip of metal in a magnetic field in which the lines of force passed at right angles to the plane of the strip. They then caused a flow of heat to pass longitudinally through the metal—in other words, they heated one end and cooled the other. Under these circumstances, when two points at opposite sides of the strip (breadthwise) were connected to a galvanometer it was found that a difference of potential existed between them, and a continuous current could be taken off so long as the flow of heat continued. That this was not a thermo-electric effect was proved by the fact that the direction of the E.M.F. was reversed by reversing the magnetic field. The difference of potential was, however, very small, and comparable to that of the "HALL effect," which, indeed, suggested the experiment in question, and which it closely resembles. In fact, it seems to us that the HINGHAUSEN-NERUST effect would almost certainly be entirely swamped in Mr. ACHESON'S experiment by the ordinary induction—if we rightly understand the conditions.

ONE further remark obviously follows. If Mr. ACHESON has succeeded in converting heat into electrical energy by a development of the HINGHAUSEN-NERUST experiment he ought not to require an *intermittent* current in the primary. The beauty of this method would consist—if it could be shown to be of any use on a practical scale—in the fact that no mechanical or electrical reaction is involved, the only source of dissipation of energy in the conversion being that due to the radiation of heat in the maintenance of two widely different temperatures in the same mass of metal. We confess that the possibility of an industrial application of the principle does not to us appear a very hopeful one, but the idea is perhaps worth following up.

IT is certainly peculiar to find a maker of series lamps introducing them to the public and at the same time pointing out *quite* so many disadvantages to their use, as is done in Mr. W. SIEMENS' paper, which we print elsewhere. To two of his points we must take some exception. First, it is not fair to take an unflashed Edison bamboo filament as a standard with which to compare his own carbon, for such filaments are not used in practical work; secondly, we doubt very much whether, while strongly attacking the Bernstein system, the author is justified in saying that the saving in leads due to series running is more than counterbalanced by the cost of cut-outs to each lamp. This comparison is made on the basis of his own cut-out, which, it seems, cost thirty shillings; whereas in the system he attacks a far simpler and neater device is used which probably does not cost thirty pence, or even farthings.

IN another column will be found the twelfth annual report of the Telegraphists' School of Science, which is conducted by Mr. W. SLINGO at the Central Telegraph Office, in connection both with the Science and Art Department and the City and Guilds of London Technical Institute. This interesting school was commenced by Mr. SLINGO—at that time a telegraph clerk in the Central Office—in September, 1876, with the object of inducing his fellow clerks to take an intelligent interest in their work and to become qualified for the technical staff. The subjects taught are mathematics, chemistry, magnetism and electricity, and technical telegraphy, and provision is made both for laboratory and workshop instruction and practice. The school has had a most successful career, and this year, in the proportion of prizes awarded, it stands at the head of the list for the entire kingdom. Although both teachers and students have had, hitherto, to give their own time to the lessons, yet, as might have been anticipated, the Department has been very willing to grant facilities for the work, and several years ago two large rooms were placed at Mr. SLINGO'S disposal. The long list of "local prizes" shows that the superior officers of the Department have, moreover, adopted a very practical form of proving their interest in the undertaking. We understand that there is now considerable probability that the school will obtain further official recognition, and we hope soon to hear that Mr. SLINGO will be enabled to devote his whole time to the work.

ALTHOUGH newspaper articles on scientific subjects are seldom instructive and often misleading, we notice with satisfaction the increasing amount of attention lately given to electric industry by the daily press. The fact seems to indicate, as one of these journals puts it, that "electric lighting is an industry which is about to spread its wings." On the same authority, however, we learn with some surprise that safety fuses are a quite recent invention, and that all or nearly all the electric-lighting plant used in this country is imported from abroad. If this were the case, we should expect the industry to soon take flight altogether.

WE learn with some surprise and not a little disgust that the project for inflicting capital punishment by electricity, broached five or six years ago, and condemned by us at the time, has again cropped up—this time in the State of New York. A commission we are told has pronounced its award in favour of the electrical method; and we have no choice but to accept the statement. But when it is added that "various

Digitized by Google

plans for applying the electric current have been proposed by rival engineers," we take leave to doubt it. That electrical engineers may be hard pressed for business, even in New York, is conceivable; but that they have entered into competition with Jack Ketch and Judge Lynch, we refuse to believe. If society has grown too squeamish to avenge itself on its enemies in the old-fashioned way, science, we feel confident, will decline to do the dirty work for it. We protest especially against associating electricity with this revolting business. What would be said of us if we suggested poisoning the culprit with gas? Mr. EDISON, we are pleased to notice since writing the foregoing, has expressed his detestation of the whole affair.

"FOUR MINUTES instead of four months, that is the measure of the shrinkage of this plastic world beneath the magic touch of the electrical engineer!" Such is the moral which the *Pall Mall Gazette* has drawn from "the most extraordinary interview on record." We should have thought that the expansion of the world, not its shrinkage, would be the idea suggested by such interviews as these. But, be that as it may, they are by no means uncommon, though not often "on record;" and the only extraordinary thing about the one described is the nonsense which the interviewers talked to each other. When telegraphists are put through to long distances—often on longer stretches than any that were spanned by the *P. M. G.* last Sunday evening—they have always something to say; on this occasion, these eminent journalists and sabbath-breakers had nothing to say, and said it at great length. Some people will, we suppose, believe, as the *P. M. G.* evidently intends they should, that "the political revolution thus effected" by a telegraph line 7,000 miles in length is the invention of that enterprising journal, just as they appear to believe that it is the author of the Seventh Commandment. Our own hope and trust is that the real authors of the telegraph lines will make the *P. M. G.* realise the shrinkage of its plastic purse for this three hours' fooling. For if the companies do not profit by it nobody else will—not even the editor of the *P. M. G.*, whose admirers, as a rule, hold the Fourth Commandment in some estimation, and will not approve of its being needlessly broken for journalistic speculations of this unedifying kind.

Copper.—A further decline has taken place in the price of copper, Chili bars being yesterday quoted £73. 17s. 6d. to £74. 7s. 6d.

The Brussels-Paris Telephone Lines.—The second telephone line between Paris and Brussels has just been completed, and will shortly be opened for traffic. This line passes through Soissons, Laon, Vervins, and Herson.

The Lighting Messrs. W. H. Smith and Son's Premises.—We are informed that Messrs. Woodhouse and Rawson have been entrusted with the wiring of the extensive premises of Messrs. W. H. Smith and Son in the Strand, in connection with an installation of the electric light.

Utilisation of Water Power at Basle.—A new canal tapping the waters of the Rhine has just been completed at Basle, and the municipal authorities are anxious to utilise a portion of the fall for lighting the town. No scheme has yet been prepared, and they are open to receive suggestions.

Electrical Watches.—A German paper announces that a company has been formed (apparently in Berlin) for the manufacture of watches to be actuated by electricity. The case contains two small cells and a small electric motor actuated by a make-and-break movement. Watches of this type have already been made, but have never hitherto been regarded as anything more than curiosities.

The Export of Telegraph Wire.—The value of telegraph wire exported during the year 1887 was £817,497, against £992,667 for the year 1886, showing a decline in the twelve months of £175,170. The exports for the month of December show an increase of £87,932 over the corresponding month last year, the export for December, 1887, amounting to £114,869.

Telegraphic Communication with Lightships.—The Board of Trade has informed the Dover Town Council that experiments are to be made, over a period of eighteen months, with an electric cable between one of the Goodwin Sands lightships and the shore. If the experiments are found to be successful, other cables will be laid between the shore and lightships in dangerous positions.

Temporary Installation at Tranby Croft.—On the occasion of a ball given last week at the residence of Mr. Arthur Wilson at Tranby Croft in honour of H.R.H. Prince Albert Victor, a temporary installation of electric light was carried out by Mr. Thomas Muse, of Hull. This is the sixth year in succession that Mr. Wilson's residence has been lighted for similar purposes by the same firm.

The Chinese Telephone Concessions.—The American journals express the fear that the death of the father of the Emperor of China will lead to the revocation of the telephone concessions recently accorded to an American syndicate. The deceased prince was at the head of the Liberal and progressive party in China, and his death will probably result in a change in the policy of the Government, which may put an end to all foreign enterprise.

Curious Experiment on Foucault Currents.—*La Nature*, in a recent number, describes a curious experiment illustrating the effect of Foucault currents. A disc of soft iron has a spindle put through it so that it can be spun like a top. When at rest or moving slowly the disc is of course attracted by the poles of a magnet. But when it turns with sufficient velocity it is repelled by the magnet. In this case the electro-magnetic reaction of the currents induced in the mass of the metal is greater than the magnetic attraction.

Researches on the Commencement of Visible Radiation.—H. F. Weber finds that a 16 candle-power, 100-volt, 0·5-ampere Siemens glow lamp is just visible in a perfectly dark room at 13·07 volts and 0·051 ampere, the filament appearing a dusky grey, which with increase of current becomes ashy grey and then yellowish grey. At 18 volts and 0·06 amperes the first trace of red appeared. The temperature of the first "grey-glow" was found for platinum to be 390deg., for gold 417deg., and sheet-iron (not freed from oxide) 377deg. The temperatures were determined by a thermo-electric couple.

The Lighting of the City of London.—At the meeting of the City Commissioners of Sewers, held on Tuesday last, Mr. J. S. Bell brought up the report of the Streets Committee, which contained an amended agreement with the Anglo-American Brush Electric Light Corporation, the latter having now agreed to the insertion of a clause requiring the deposit of caution money before commencing the work. Very few members being in attendance at the time, it was agreed that the report should

Digitized by Google

be printed and circulated amongst them, and should be considered at an early hour at the next meeting of the Court. Some of the daily papers have stated that the company agreed to abandon their claim for a monopoly of the public supply of current in the district to be lighted. This statement is, however, inaccurate.

Conversazione of the Employes of the Edison and Swan Company.—A *conversazione* and concert of a very interesting character was held at the Edison and Swan Company's Works, Ponder's End, on Tuesday evening, 17th inst. Nearly the whole of the *employés* accepted the invitation of the manager, Mr. Gimingham, to whose kindness the entertainment was due. An excellent programme was provided, to which the more musical section of the *employés* largely contributed. The accompaniments were played by Mrs. Gimingham and one or two of the young ladies in the factory. The rooms were draped with flags, and the light from coloured incandescent lamps, which were hung about the room, made the decorations look very effective. Light refreshments were provided in an adjoining room. The arrangements were carried out under the direction of the works foreman, Mr. Robson.

Note on the Reading of Dial Instruments.—In order to obviate the effect of parallax in taking readings from a needle moving over the face of a dial, instruments are frequently provided with a mirror underneath the needle, so that when the image of the needle is hidden from the eye by the needle itself we know that the true reading may be obtained. In a note to *La Lumière Electrique*, M. F. Drouin points out, however, that even when no mirror is provided it is easy to take an accurate reading provided that the dial be enclosed by a cover of plane glass parallel to the needle. If a small parallelopipedon of flint glass (or any substance having a different refractive index from that of ordinary glass) be placed over the needle against the outer face of the glass cover, so long as any parallax exists the needle will appear broken—that is, the part seen through the parallelopipedon will appear displaced from the straight line. When the needle is viewed perpendicularly over the dial this effect disappears.

The Telephone at the Brussels International Exhibition.—The Administrative Council of the Brussels Exhibition has determined to make a great feature of the display of telephonic apparatus. A large number of telephone call stations will be erected in the Exhibition and all the restaurants, places of entertainment, &c., will be connected to a central telephone exchange within the building, which will be open to public inspection. It is hoped that there will be here represented all the different arrangements now employed by the telephone companies, and especially the latest improvements in switchboards. It is also intended to connect the Exhibition with the Brussels Exchange, from which, as our readers are aware, trunk wires radiate to many towns in Belgium, and it will therefore be possible for visitors to the Exhibition to speak from any call office to their friends in many parts of the country, and even as far as Paris. The Council invites participation of all telephone companies, and communications should be addressed to MM. Mourlon and Bandsept, 22, Rue des Palais, Brussels.

"The Diseases of Dynamos."—"W. H." writes to the *Electrical World*, of New York, as follows:—I have read with much interest in the *Electrical World* of Dec. 17th the article on "The Diseases of Dynamos," by Silvanus P. Thompson, in which is mentioned a small dynamo that gave trouble at the brush rocker. At one time the writer had some trouble with the insulation under the brush clamp and rocker of a Brush dynamo which caused short-circuiting. Although nothing serious came of it, it was, nevertheless, very annoying. I believe the insulation was of fibre. For a remedy, we tried several kinds of insulation, such as mica and asbestos, but they did not last. I think the trouble was largely due to copper dust from the commutator falling on the insulation and thus making cross connection. Finally, some two years ago, we tried an insulation of slate a little larger than the brush clamp, and since then have had no trouble. I think the good results are due from the slate being waterproof and smooth on its edges. I have mentioned this, as it may be of interest to some of the readers of the *Electrical World*, who have had similar trouble with insulation in wet or dusty places.

The Volta Prize.—The Commission appointed by the French Government to award the Volta prize of 50,000fr. for the most important application of electricity has recommended that it should be awarded to M. Gramme. It is not probable that anyone in this country would be disposed to challenge this decision. A choice of this kind necessarily entails more or less invidious comparisons, but in this case no one would for a moment suggest that M. Gramme's services in advancing the practical application of electricity are not entirely adequate to such a distinction. In France, however, the award has failed to give complete satisfaction. The *Paris* enters a vigorous protest against the decision of the Commissioners, and champions the claims of M. Gaulard, as the inventor of the transformer. It is undeniable that M. Gaulard was instrumental in forcing the transformer upon the attention of the scientific world, and for this he unquestionably deserves thanks and praise. But there are very few electricians, in this country at least, who would opine that M. Gaulard's achievements rank with those of M. Gramme; and this at least is not the view of the commissioners of the Volta prize.

Walker's Portable Miners' Electric Lamp.—This lamp is at present made in two forms, one of round and the other of oval section. The round form contains two cells of a zinc carbon bichromate battery in the oval pattern. There are three such cells. The carbon of the battery itself forms the containing vessel. Externally on one side of the case is a lens faced by a parabolic reflector, the two being held by a strong brass cylinder attached to the outer case, which is also of brass or copper. The cells contain the usual porous pots and zincs, and are closed by an india-rubber pad, above which the connections are made in a simple and efficient manner. A second pad of india rubber is placed above this, and is retained in its place by the cover, which is held by screws or a lock, as desired. A stout handle surmounts the whole. The smaller lamp is made of cylindrical form, weighs 5lb., and gives a light for ten hours sufficient to read ordinary newspaper print at 6ft. from the lamp. The cost of renewing the chemicals, the incandescent lamp, and incidental repairs, is stated to be not more than ¾d. per day for the small lamp, and 1d. per day for the larger type. We are glad to learn that the introduction of electric light is making rapid progress in the South Wales colliery district.

Royal Meteorological Society.—The monthly meeting of this society was held last week at the Institution of Civil Engineers, Mr. W. Ellis, president, in the chair. The paper read was on "The Non-Instrumental Meteorology of England, Wales, and Ireland," by Mr G. M. Whipple. Mr. Ellis, in his presidential address, reviewed briefly the work and position of the society, remarking that such a society, whilst unable to carry out expensive, original, or experimental work, could yet act with great advantage in inciting volunteer workers throughout the country to united action, of which one recent example was the

Digitized by Google

ready response to the request of the society for photographs of lightning, an excellent collection of which had been attained, and would shortly be exhibited. Referring to the question of sympathetic relation between sun-spots and magnetism and meteorology, he thought that any complete treatment of the question in its meteorological aspect seemed to require that it should be dealt with in a much more comprehensive manner than before, for which purpose observations more completely covering the surface of the globe might be necessary, if indeed not necessary also for the solution of many other meteorological questions, the present meteorological stations being distributed over the earth in such isolated clusters.

The Heeling Error of the Compass in Ships.—At a recent meeting of the Philosophical Society of Glasgow Mr. Wm. Bottomley read a paper on "The Heeling Error of the Compass in Ships." He did not propose to enter into the general question of the magnetism of an iron ship and the errors of the compass which it produced, but would confine himself to the consideration of the disturbance which was experienced when the vessel heeled over. He would assume that with the ship on an even keel the effect of the magnetism of the ship's iron on the compass had been compensated by Airy's well-known plan of placing magnets fore and aft and thwartship to correct the semicircular error and masses of soft iron on each side of the compass for correcting the quadrantal error, and that the compass was correct on all courses when the ship was on an even keel. When the ship heeled over the altered position of the iron of the ship produced a change in its effect of the compass and gave rise to the heeling error. The disturbance due to heeling arose from two separate causes—first, the component of the ship's permanent magnetism which is perpendicular to the deck; and, second, the magnetism induced in the soft iron of the ship by the vertical component of the earth's magnetism. It was with the error produced by the second of these causes the lecturer dealt. That was by the magnetism induced in the soft iron of the ship by the earth's magnetic force, and he also showed that the masses of soft iron which were placed on each side of the compass to correct the quadrantal error when the ship was upright exercised a most important part in correcting the heeling error when the ship heeled over if they were fixed to the binnacle and moved with the ship.

The Thomson-Houston System in Brussels.—Lighting of the Moliere Theatre.—Our Brussels correspondent writes :—"A branch of the Thomson-Houston International Electric Company has been formed in Brussels under the title of the Belgian Thomson-Houston Electric Company, of which M. A. Admirallie is manager, and partly with Belgian and partly with American capital. A central station has been established in the Chaussée de Wavre, near the Porte de Namur, for lighting by contract at the same rate per candle-power that gas is now charged. Operations were begun definitely on 15th January, the lessee of the Molière Theatre, which is now lighted entirely by electricity, being the first and principal subscriber. The installation of the central station includes a forty indicated horse-power horizontal engine by Mennig Frères, of Cureghem-Bruxelles, the steam distribution of which is effected in a very simple yet effective manner, giving great regularity. A horizontal shaft, parallel with the centre line of the engine, carries two-edge cams for opening the steam valves, which are closed by other cams and levers assisted by springs, while a face cam opens the exhaust valves. The shaft is shifted laterally by a lever actuated directly by the governor for giving greater or less admission of steam. There are at present two dynamos, capable of maintaining, one thirty 1,200-candle arc lights, and the other 250 small incandescent lamps. The Molière installation includes two 1,200-arc lamps, one outside the theatre and one in the middle of the central chandelier, a 65-candle and five 32-candle incandescents, all in one circuit, and also a separate circuit for the stage, with about 200 incandescents of 10 and 16 candles, for the footlights, borders, and battens. By thus running the lamps in separate circuits, if a fire should break out on the stage, and the iron curtain descend, as it would, automatically, the lamps in the front of the house would be unaffected. Nine different degrees of brilliancy can be given to the lamps, thus leaving nothing to be desired as regards stage effect. By means of the Thomson-Houston regulator any lamp can be switched off without affecting the others, even momentarily, nor is there any need of introducing resistance coils. M. Alhaiza, the manager of the theatre, expresses himself perfectly satisfied with the lighting, both arc and incandescent lamps being absolutely constant."

Electric Lamps in the Welsh Collieries.—The following letter, written by a gentleman whose knowledge of mining affairs is described as authoritative, appeared recently in the *Evening Citizen*, of Glasgow:—"I have waited for another opportunity of seeing the electric lighting before replying to your letter, as I wanted to be able to give accurate information. I saw 200 lamps at work, and I formed a very favourable impression as to the success of the system. Indeed, I see nothing to prevent their general adoption, and I am satisfied that the men like them. The weight is 7lbs., but that does not appear to be an obstacle, although it would doubtless add to their value if a good enough light could be had by a lamp of less weight, say 4lb., about the weight of an improved safety lamp. You see the men at the face have only to carry them in and out, and they do not object to carrying 7lb. in a handy shape. The light is equal to 8 or 10 Clanny lamps at the start, it gets less towards the end of the shift, but at the end of 10 hours is still better than a Clanny. The men like them. As to the cost, I believe they will not cost more than £1, but this is only a guess. The time is too short to tell what the cost of upkeep will be, but, judging from electric lighting on the surface, the cost will not be heavy, and will probably be *much less* than that of ordinary safety lamps. The chief item of cost will be the renewal of the glow lamp, and as these are much smaller than the ordinary glow lamps, their cost will not be much, perhaps 2s. 6d. The lamp burns at its full capacity from the beginning, the idea of reserving so much force and manipulating the light after a few hours having been abandoned. The aim is to have a good enough light at the end of, say, ten hours. A defect at present, but one which is to be remedied, is that as soon as the lamp is put together it must burn, and so in the giving out of lamps a large number may be burning an hour before they are actually needed. The arrangement of charging is simple in the extreme—a boy can manage several hundreds. They are placed in series on tables, 60 in a block, and remain seven or eight hours. An index lamp burning in front of each row of eight shows when the lamps in that row are charged by its light getting dim, the current *skipping* the row then, and, of course, not going through the index lamp with the full strength of current. The battery portion of the lamps are exactly the same, and fit any one of the square receptacles on the table. After the lamps have been a few days in use (it takes a few days to get them into trim, to get *saturated*, as it were, or into the proper condition to absorb the electricity), they burn well for ten hours, and no one now need be afraid to go in for them."

EARLY RESEARCHES IN THERMOMAGNETIC GENERATORS.

(Concluded from page 258.)

At the Loan Exhibition of Scientific Apparatus, held at South Kensington in 1874, Dr. G. Gore exhibited an apparatus which is illustrated in the adjoining figure, and which appears as No. 1,136 in the third edition of the Catalogue under the title "Apparatus for Showing a Series of Molecular and Magnetic Changes in an Iron Bar."

In the figure A is a horizontal bar of iron fixed to the apparatus securely at its left-hand extremity; B a coil of thick copper insulated wire surrounding the bar and connected with a battery; C a coil of thin copper insulated wire, also surrounding the bar, with its ends attached to a distant galvanometer; D a removable lever, weighted at its free end, for exerting compression by means of a transverse iron axle and clutch, F, upon the iron bar lengthwise. By reversing the position of this lever to that of the horizontal dotted lines, it exerts traction upon the iron bar; E another removable weighted lever, fixed upon the free end of the iron bar, which in the position given exerts right-handed torsion upon the bar, but if transferred to that shown by the dotted lines, exerts left-handed torsion. The levers may be used either singly or combined. If the bar be heated to redness at its middle part to a temperature above that at which it suddenly loses a large portion of its magnetic capacity, the influence of mechanical compression, extension, and torsion, either singly or combined, upon the peculiar molecular changes, can be examined. Screens are placed between the flames and the coils to protect

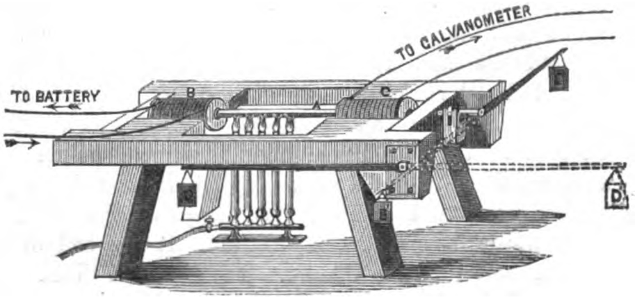

Fig. 2.

the latter from the heat, and sometimes pieces of firebrick are placed on each side of the heated part of the bar to concentrate the heat, as in an ordinary tube combustion furnace.

The proposed experiments on the effects of strain and torsion were never carried out by Dr. Gore, but he made a careful examination of the thermo-magnetic properties of iron and nickel, and the conclusions arrived at will be found in the *Phil. Mag.*, Vol. XL., 1870, p. 175. It will be found that these conclusions are quite in harmony with the later and more complete results which we published last week, and the investigation, though to some extent superseded by these later researches, has yet a good deal of interest of its own. The following is the portion of the paper which refers to nickel, and is therefore the most interesting at the present time:—

"With a bar of cast nickel about 18in. (=45·7 centims.) long and ½in. (=12·7 millims.) thick, the following effects were obtained:—During heating a slow deflection of 1¼deg. was obtained at a particular temperature much below a red heat; and during cooling a deflection of 1½deg. in an opposite direction occurred, apparently at the same temperature; no other deflections were obtained by heating the bar gradually to redness and then cooling. With another bar of that metal, 2ft. long and ¾in. in diameter, a thick wire coil 6in. long and 2¼in. (=5·7 centims.) in diameter, containing eight layers, or 536 turns of 'No. 17' copper wire, and a thin wire coil 6in. long and 2in. in diameter, containing 14 layers or 1,960 turns of 'No. 27' copper wire, on applying the full heat of five small Bunsen's burners, in about four minutes the needles were rather suddenly deflected 2¼deg., with irregular action at a particular temperature, not even approaching that of the lowest visible redness in the dark; and by heating to a much higher temperature, but still below redness, faint signs of a second similar molecular disturbance in the same direction were manifested. The heat being now stopped, and the bar allowed to cool gradually, the same phenomena, and to the same extent, took place, but in an exactly reverse order. On repeating the experiment with this bar, but cooling the bar rapidly by continuous application of cold water, a sudden deflection of 8deg. occurred when the bar acquired the proper temperature. The direction of all the deflections with this bar (as with nearly all the previous bars) during heating agreed with those producible by a *decrease* of magnetism, and during *cooling* with an *increase* of magnetism. By substituting for the fine-wire coil another, containing 3,600 turns of size 'No. 29' (=0·28 millim. thick) copper wire, very feeble results only were obtained, the coil itself offering too great a degree of conduction-resistance.

"In these experiments with wrought iron, steel, cast iron, and nickel there is a very *gradual* magnetic change, in addition to the several sudden or irregular molecular movements and changes of magnetism; this gradual change is manifested by a very faint deflection of the needles in the same direction as those produced by most of the sudden movements."

In another paper in the *Phil. Mag.*, Vol. XL., 1870, "On the Magnetism of Electro-Dynamic Spirals," Dr. Gore describes some experiments of a simple and easily repeated form which are admirably adapted for the lecture table. Figs. 3 and 4

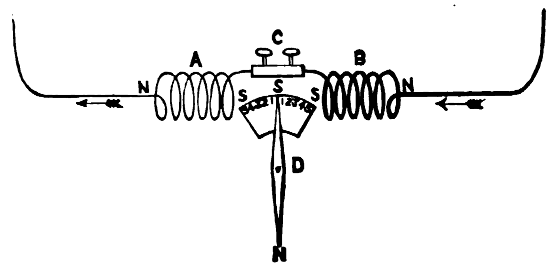

Fig. 3.

illustrate these experiments. Two spirals, A and B (Fig. 3), having the same number of turns but of different metals, are connected together at C, and a strong current is passed through them. A compass needle is brought between the spirals, and

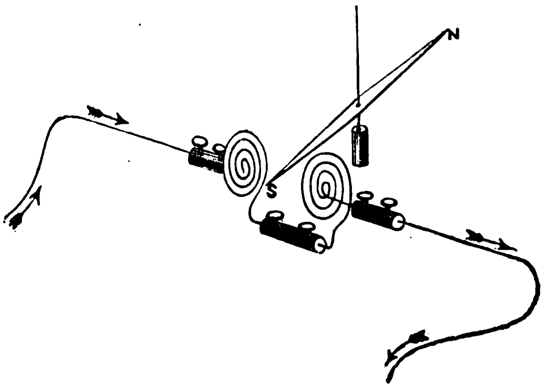

Fig. 4.

the winding is so arranged that the pole of the needle remains in equilibrium, being repelled by each spiral equally. Now with two non-magnetic metals, say, German silver and platinum, the spirals being in series, the current may be increased to any extent, heating the wires to redness, without at all affecting the equality of the action, and the needle remains in equilibrium. But if the same experiment be repeated with one coil of iron, and the other, say, of platinum, the phenomena are of a much more complex character. First, with no current in the coils, the needle is attracted to the iron; but when a small current flows, this attraction is presently overcome by electro-dynamic repulsion, and as the current is increased the power of the iron spiral gradually becomes equal to, and at length exceeds, that of the platinum. This is due to the fact that while the electro-dynamic (or solenoidal) action of the two spirals remains the same, the iron possesses also a molecular magnetisation of its own which is induced by the current. Suppose, however,

Digitized by Google

that at this stage a balance is restored, which can be done most conveniently by bringing the pole of a magnet to the assistance of the platinum spiral. Then, if we continue to increase the current, in order to maintain the balance, we shall at first have to bring the compensating magnet nearer and nearer. But by-and-bye, as the iron approaches a bright red heat (or, as we now know more exactly, a temperature of 700deg. C.), the iron suddenly begins to lose its molecular magnetisation, until at 780deg. C. the platinum spiral is again able to maintain a balance without the assistance of the magnet, the iron now acting as a non-magnetic metal.

Fig. 4 is only a modification of the same experiment.

NOTES ON ALTERNATE CURRENTS.

BY J. A. FLEMING, M.A., D.SC.

(Continued from page 237.)

We require in the next place to find the value of the mean of the square of the ordinates to the same curve, assuming them to be equi-distant and infinite in number. If y_1 y_2, &c., are the ordinates, and n the number, we require to find the value of

$$\frac{1}{n}\left(y_1^2 + y_2^2 + y_3^2 + \&c.\right)$$

as above ; the value of any ordinate being

$$y = A \sin \frac{\pi}{l} x.$$

Hence, if $X X' = l$ is divided into n intervals, each equal to δx, so that $n \delta x = l$, we have to find the value of

$$\frac{A^2}{n}\left(\sin^2 0 + \sin^2 \frac{\pi}{l}\delta x + \sin^2 \frac{\pi}{l} 2\delta x \quad . \quad . \quad . \quad + \sin^2 \frac{\pi}{l}\overline{n-1}\,\delta x\right);$$

but since
$$\sin^2 \theta = \frac{1}{2}\left(1 - \cos 2\theta\right),$$

the series in the bracket can be replaced by

$$-\frac{1}{2}\cos 0 + \frac{1}{2} - \frac{1}{2}\cos\frac{\pi}{l} 2\delta x + \frac{1}{2} - \frac{1}{2}\cos\frac{\pi}{l} 4\delta x + \&c.$$
$$. \quad . \quad . \quad . \quad + \frac{1}{2} - \frac{1}{2}\cos\left(\frac{\pi}{l} 2n\delta x - \frac{\pi}{l} 2\delta x\right)$$

for n terms. Hence the mean value M is

$$M = \frac{A^2}{n}\frac{n}{2} - \frac{A^2}{2n}\left(\cos 0 + \cos\frac{\pi}{l} 2\delta x + \&c.,\right)$$

for n terms.

The cosine series forms a progression of terms which begins with unity, since $\cos 0 = 1$ and passes down through zero to -1, and then up from -1 through zero to unity again,

since
$$\cos\left(\frac{\pi}{l} 2n\delta x - \frac{\pi}{l} 2\delta x\right) = +1,$$

when $n \delta x = l$.

Since the angles are in arithmetic progression we can pick out from this series pairs of cosine terms, such that they are equal in magnitude but opposite in sign, and hence, taken pair and pair, they cancel each other out, and leave the sum of the cosine series in the bracket equal to zero, and hence

$$M = \frac{A^2}{2},$$

that is the mean of the values of all the ordinates squared taken equi-distant and infinite in number is half the square of the maximum value.

We have, therefore, this result. If the current in a linear conductor varies in strength and direction in a manner which geometrically would be represented by the ordinate of a simple sine curve, then the true mean value of the current strength is $\frac{2}{\pi}$, or ·637 of its maximum value, and the mean value of the square of the current strength taken at equal and very small intervals is half the value of the square of the maximum.

Since $\frac{2}{\pi} = \cdot 637$ and $\frac{1}{\sqrt{2}} = \cdot 707$, and since the difference $= \cdot 07$, the true mean current is less than the square root of the mean of the squares at each instant by an amount which is very nearly 10 per cent. of the latter.

The next geometrical proposition to which we pass is one of some importance.

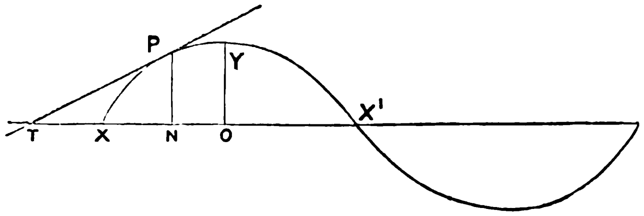

FIG. 14.

Let the curve in Fig. 14 represent the complete period of a simple periodic curve of which the equation is $y = A \sin \frac{\pi}{l} x$. Let P be any point on the curve, then $P N = y$, $O Y = A$, $X X' = l$. At P draw a tangent P T to the curve, and let it meet the datum line at T.

We shall call the trigonometrical tangent of the angle P T N, the *slope* of the tangent at the point P, hence $\frac{P N}{T N}$ = the slope.

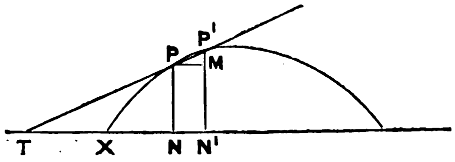

FIG. 15.

If two points, P P' (Fig. 15), are taken on the curve very near together, and a secant, P' P T, drawn through them, this secant will become a tangent when the points P P' move up into contact. The ratio of $\frac{P' M}{P M}$ will then, in the limit, become the slope of the tangent. If, now, $X N = x - \frac{\delta x}{2}$ $X N^1 = x + \frac{\delta x}{2}$, and $P M = N N'$ is δx, we have the equations

$$P N = A \sin\frac{\pi}{l}\left(x - \frac{\delta x}{2}\right)$$

and
$$P' N' = A \sin\frac{\pi}{l}\left(x + \frac{\delta x}{2}\right)$$

and
$$\frac{P' M}{P M} = \frac{A}{\delta x}\left[\sin\frac{\pi}{l}\left(x + \frac{\delta x}{2}\right) - \sin\frac{\pi}{l}\left(x - \frac{\delta x}{2}\right)\right]$$

The quantity in the bracket is identically the same as

$$2\cos\frac{\pi}{l} x \sin\frac{\pi}{l}\frac{\delta x}{2},$$

and hence

$$\frac{P' M}{P M} = \frac{A}{\delta x}\frac{\pi\,\delta x}{l\ 2}\,2\cos\frac{\pi}{l}x\left[\frac{\sin\frac{\pi}{l}\frac{\delta x}{2}}{\frac{\pi}{l}\frac{\delta x}{2}}\right]$$

$$= \frac{A\pi}{l}\sin\left(\frac{\pi}{l}\left(\frac{l}{2} - x\right)\right)\left[\frac{\sin\frac{\pi}{l}\frac{\delta x}{2}}{\frac{\pi}{l}\frac{\delta x}{2}}\right]$$

Digitized by Google

When $\delta x = 0$, the quantity in the square brackets is unity, and we have

$$\text{slope} = \frac{A\pi}{l} \sin\left(\frac{\pi}{l}\left(\frac{l}{2} - x\right)\right).$$

If we plot a curve whose ordinates at any point are the slope of the primal curve at the corresponding points, the above equation shows us three things—first, that it is a sine curve or simple periodic curve of the same type as the curve from which it is derived; second, that its maximum value is $\frac{\pi}{l}$ times the maximum value of the original; and third, that its zero ordinate corresponds to the maximum one of the original, and *vice versâ*.

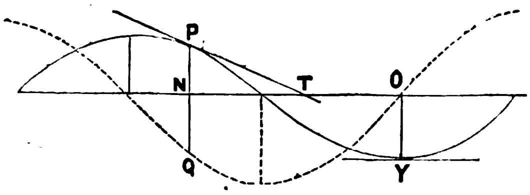

Fig. 16.

In Fig. 16 the firm line curve is a curve of sines

$$y = A \sin \frac{\pi}{l} x,$$

the dotted line is a curve of sines, whose ordinate Q N at any point represents the *slope* of the tangent at P on the original curve. Accordingly at Y, where the original curve is at its maximum, and the slope of its tangent is zero, the derived curve cuts the datum line, or has its phase shifted 90deg. backwards relatively to the original curve. In the language of the differential calculus, the firm line curve is the plotting of $y = A \sin \frac{\pi}{l} x$, and the dotted curve is the plotting of $\frac{dy}{dx}$ as ordinates for the same abscissæ. We may regard it from another point of view. Let the simple sine curve be supposed to be generated, or marked out by a tracing point, P, which moves to and fro along a line P N P′ with a simple harmonic motion, whilst the point N moves uniformly along a straight line X X′. (See Fig. 17.)

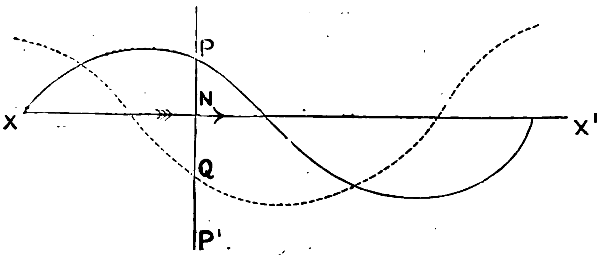

Fig. 17.

Draw as before the dotted curve whose ordinate Q N at any point represents the slope of the firm curve at the corresponding point P. Then the magnitude of N Q will represent the *rate* at which the ordinate P N is increasing or decreasing. For in this case, distances such as X N, measured along the mean line, are proportional to time, and hence N makes a small movement forward in a small time dt; there is a corresponding decrease in the ordinate P N, which we may denote by dy, and accordingly $\frac{dy}{dt}$ represents the rate of decrease of P N. If the small forward movement of N causes N to advance through a space dx, dx is proportional to dt, as the motion is uniform, and accordingly $\frac{dy}{dx}$ is proportional to $\frac{dy}{dt}$, hence $\frac{dy}{dt}$ is at any instant graphically represented by the slope of the tangent at P—that is, by the ordinate P′ N. The dotted curve represents, therefore, the *rate of change* of the ordinates of the firm curve at that same instant. We shall call the dotted curve the *derived curve*.

If the original curve represents a simple periodic current flowing in a conductor, the derived curve will represent the *rate of change of that flow* at each instant. The derived curve is a similar curve, but shifted backwards by one quarter wave length, so that its crests coincide with the hollows of the original curve, and *vice versâ*.

MR. STANLEY ON THE COMPARATIVE COST OF DISTRIBUTION BY DIRECT CURRENTS AND BY TRANSFORMERS.

In a paper lately read before the Boston Society of Arts Mr. Stanley gave the following figures as representing approximately the comparative cost of distributing electrical energy by the three wire system and by transformers:—

Distance, 3,000 feet. No. Lamps, 10,000. Maximum per cent. of Loss, 5 per cent. Copper at 18 cents per pound.

200-volt Edison "3-wire" System.	1,000-volt Induction System.
Conductors cost $126,634.00	Conductors cost $2,658.00
	Converters 30,000.00
	Total $32,658.00

Distance, 300 feet. No. Lamps, 500. Loss, 2 per cent.

Edison "3-wire" System.	1,000-volt Induction System.
Cost of Mains $156.00	Cost of Mains $3.60
	Cost of Converters 1,500.00
	Total $1,503.60

Edison "3-wire" 200-volt System.				1,000-volt Induction System.		
Per cent. of Loss in Mains.	Distance.	Number of Lamps.	Cost of Mains.	Cost of Mains.	Cost of Converters.	Total.
2	1,000	1,000	$3,511.00	$84.00	$3,000.00	$3,084.00
5	1,000	1,000	1,347.00	33.00	3,000.00	3,033.00
2	1,500	1,000	7,910.00	197.00	3,000.00	3,197.00
5	1,500	1,000	3,156.00	78 00	3,000.00	3,078.00
2	2,000	1,000	13,952.00	330.00	3,000.00	3,330.00
5	2,000	1,000	5,675.00	141.00	3,000.00	3,141.00
2	4,000	1,000	56,282.00	1,407.00	3,000.00	4,407.00
5	4,000	1,000	22,512.00	562.00	3,000.00	3,562.00

The paper continued as follows:—"From this table we see that at the present cost of converters, the two systems cost the same, with 2 per cent. loss at 1,000ft. distant, with 5 per cent. loss at a distance of 2,500ft. distribution; and at 5 per cent. loss the three-wire system is the most economical for shorter distances, while the induction system costs less for greater distances.

"The distribution of electrical energy by means of the high potentials and induction coils has almost annihilated the cost for the mains, while it has introduced the item of cost of converters. At present prices for converters and copper at twenty cents per pound, fifteen pounds of copper equal the cost of one lamp capacity in converters, and the purchaser has an equal option of using either the three-wire or converter system when distributing current at a distance of 1,100ft., with 2 per cent. loss; 1,500ft. with 5 per cent. loss, &c."

Mexican Import Duties upon Telegraph Material.—The *Two Republics* says that a notification has been published by the *Diario Oficial* exempting from duty posts, cross-trees, sticks, and conductors for telegraph and telephone lines.

AUTHORSHIP OF ELECTROLYTIC THEORY.

(Translation of a Letter from Prof. Clausius, received by the Secretary of the Electrolysis Committee of the British Association.)

Bonn, 2nd October, 1887.

Dear Sir: While I render you my best thanks for kindly sending me the Report of the E.C.B.A., which I have read with much interest, I should like to be allowed to make a remark on one point arising in it. You mention the theory of electrolytic conduction, started by me in the year 1857, by the name, "the old Williamson-Clausius hypothesis;" and in similar terms my theory is referred to in other parts of the circular you have been good enough to send me.

This nomenclature must arouse in the minds of readers not fully conversant with the literature of the subject a question as to whether Williamson has not also devised a theory to explain electrolytic conduction.

This, however, is not the case. Williamson was only considering a purely chemical process, namely, the formation of ether, and his theory relating to this was contributed to the British Association in Edinburgh. On electrolytic conduction he had not spoken a single word. I am quite convinced that he himself has not the least intention of claiming the merit of having started a hypothesis for the explanation of electrolytic conduction.

By other authors the theory of electrolytic conduction is continually referred to as mine. Of English authors I will only mention Maxwell, who, in his "Treatise on Electricity and Magnetism," Vol. I., p. 309, speaks of "the theory of Clausius" simply.

I trust, therefore, that you will kindly arrange so that terms conveying a meaning not intended by the Committee may be avoided by them, lest they excite a false impression in the minds of readers.—With assurances, &c., faithfully yours,

R. CLAUSIUS.

REMARK BY DR. OLIVER LODGE ON THE ABOVE LETTER OF PROF. CLAUSIUS.

I have the greatest pleasure in bringing before the notice of the E.C.B.A. the remonstrance of Prof. Clausius, and shall hope to receive instructions from them at their next meeting. Meanwhile I may be permitted to state that the reason the nomenclature objected to has been so far partially and provisionally adopted is to be found in a paper by Dr. Williamson published in Liebig's *Annalen (Ann. d. Chem. u. Pharm.)*, Vol. 77, page 45, 1857. I merely mention this fact, without presuming to judge the question in any way.

O. L.

ON THE PROPERTY OF THE ALKALIES OF INCREASING THE E.M.F. OF ZINC.

It is now more than thirty years since Grove, Joule, Poggendorff, and others observed that the E.M.F. of the cells then in use was increased by replacing the dilute acid by a solution of caustic potash or soda. In a paper in the November number of *Wiedemann's Annalen* Herr J. H. Koosen gives an account of some recent investigations which he has made on this phenomenon. He points out that the increase must be due to chemical action, and not merely to the contact electrification. Numerous researches which have been made by the author prove, he considers, beyond a doubt, that the caustic alkali, to fix the ideas say potash, gives rise to a fourfold action.

(1). Caustic potash breaks up into its constituents. (2). Potassium takes the place of zinc in the electrical action of the cell. For example, in a Daniell's cell potassic sulphate (K_2SO_4) is formed in place of zinc sulphate, copper being deposited as in the ordinary arrangement. (3). The zinc is oxidised by the action of the oxygen of the caustic potash (KHO). (4). The resulting oxide of zinc is dissolved by the solution of potash.

(1) diminishes the E.M.F., (2) and (3) increase it. With regard to (4) Favre and Silbermann's researches tend to show that it is merely of the nature of local action, and therefore does not contribute to the electrical energy of the cell. It might, however, possibly slightly increase the E.M.F., but the effect would necessarily be very small, as the heat of combination of zinc oxide and potassium is only about 2 per cent of that produced by the decomposition of zinc in a Daniell cell. That the chemical actions are as described may be shown by dropping sulphuric acid into the zinc cell, when a white precipitate of oxide of zinc is produced, while in the other cell, the copper one in a Daniell, potassic sulphate is formed instead of zinc sulphate, and is deposited in the porous cell. The character of the cell is thus entirely changed, zinc only serving by its affinity for oxygen to facilitate the decomposition of the caustic potash. The author has limited his researches to the Daniell and a few other simple cells, as very little is known about the chemical action which takes place in most of the cells in general use.

Let the E.M.F. of an ordinary Daniell be assumed as the unit of E.M.F., and let the unit of heat be the amount generated in a Daniell cell by the decomposition of n grammes of zinc, where h is the atomic weight of that element.

If the external resistance be very great, practically the whole heat of chemical combination will be developed in the external circuit. Thus, from Thomsen's determinations, the E.M.F. of a Daniell is given by $Zn\,SO_4$ (248) - $Cu\,SO_4$ (198) = 50 = 1 Daniell. When potassium hydroxide (KHO) is used in place of sulphuric acid, K_2SO_4 (337) + $2Zn\,OH_2O$ (166) - 2 KHO (232) - $Cu\,SO_4$ (198) = 73 = 1·46 Daniell. For some of the other cells tried by him $Zn\,Br_2$ (91) = 1·82 Daniell; $Mg\,Br_2$ (165) = 3·3 Daniell; $K_2\,Br_2$ (180) = 3·6 Daniell; and for a zinc-potassium-bromine cell, $K_2\,Br_2$ (180) + $2Zn\,OH_2O$ (166) - 2KHO (232) = 114 = 2·3 Daniell.

From a practical point of view the author finds a Daniell with caustic alkali to be a good form of cell for giving long-continued currents through a large resistance. The chief point to be observed in using such a cell is to prevent, as far as possible, any diffusion taking place between the two fluids. The author has succeeded in effecting this by the use of a double porous cell containing a solution of potassic or sodic sulphate, as the case may be, and he finds that if a little sulphuric acid is added to this solution to improve its conductivity, the resistance of the cell is not very greatly increased. The alkaline solution must not be too dilute, or the zinc will soon become coated with oxide. Soda he finds preferable to potash, because, being more soluble in water, it does not so soon crystallise on the porous cell, thereby increasing the internal resistance.

The author considers that a zinc-platinum-bromine cell is far superior even to this modification of a Daniell for giving continuous currents through a high resistance. It requires no porous cell, and has been kept joined up through a large external resistance for four months without showing any perceptible diminution in its high E.M.F., which remains constant until one or other of the elements is entirely decomposed. The only precaution required is to cover the bromine with a layer of petroleum a few millimetres in thickness, which entirely prevents all smell or evaporation.

G. W. T.

THE LINEFF AND JONES ELECTRICAL TRAMWAY.

On Wednesday last we had an opportunity of examining an electric tramcar, designed to run on the "conduit" system, by Messrs. Lineff and Jones. The trials took place on the lines of the West Metropolitan Tramway Company, at Chiswick.

The car is of small size, being built to carry 20 passengers, and is fitted with a series-wound motor by the Immisch Company, running at 1,000 revolutions per minute, with 10 amperes at 230 volts, when the car is travelling at six miles an hour. The power is transmitted from the pulley of the motor by a Renold's chain to one of the axles, gearing down ten times. The current was supplied by a series-wound Immisch dynamo. In the middle of the track is a culvert

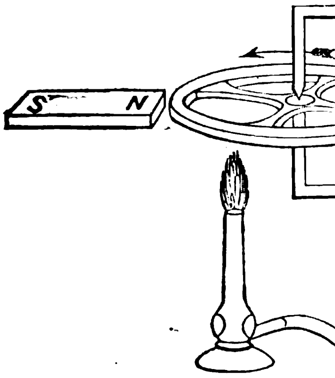
Digitized by Google

1ft. 7in. deep, formed of concrete, into which is built every two or three feet a sort of deep U-shaped chair. The legs of the U chairs support two longitudinal rails, which close the culvert all but a narrow slit $\frac{3}{4}$in. wide. The conductor is a bare No. 12 copper wire, run in screwed gas-barrel. This latter is held at each chair by a bracket, from which it is insulated by a serving of insulating tape. Iron forks are scrèwed into the barrel every few feet, their ends clamping down on the copper wire inside to secure good contact. The conductor is run well to one side of the culvert, so as to be clear of any dirt or water dropping through the slit. A flat iron plate at each end of the car runs in the centre slit, and between the two plates inside the culvert is hung a flexible conductor consisting of brass "beads" some two or three inches long and $\frac{3}{4}$in. diameter strung on a piece of stranded wire cable. This conductor rests in the iron forks on the gaspipe, never making contact with less than four at once, and, as far as we could see, picks up the current without any appreciable sparking. The lower part of the plate is, of course, bent to one side, so that the flexible conductor hangs in the line of the forks. The return circuit is through the side rails. The car is fitted with a break, worked by a long pull magnet, and the "cow-catcher" in front of the car is so arranged that on meeting with any obstruction it instantly reverses the motor. The lighting was by glow lamps, three in series, which were naturally anything but steady when the car was stopping or starting.

The chief feature which is special to the system is the method of making contact between the car and the fixed conductor, and this certainly appeared to answer the purpose extremely well, though it is of course impossible from a single trial run to form a definite opinion as to the merits of the device when employed on a large scale. Beyond this, there is nothing very novel in the system.

SCHWEDOFF'S THERMO-MAGNETIC MOTOR EXPERIMENT.

In reply to several requests for further information upon the experiment of Schwedoff, to which reference was made in



our recent article on M. Menges' thermo-magnetic generator, we produce herewith a sketch from which it will be readily understood. An iron ring is provided with four brass spokes, by which it is pivoted at the centre so as to be free to rotate in its own plane. A steel magnet is brought near one side, and at a distance of about 45deg. a Bunsen burner is placed. The magnetic permeability of the iron being greatly weakened by the heat from the flame, the effect is the same as if this part of the ring were made of brass or some other non-magnetic material; consequently the magnet tends to pull the ring round in the direction of the arrow, so as to restore the symmetry of the field. But as the hot part rapidly cools when removed from the flame, and the adjacent section is heated, the distribution of temperature, and therefore of magnetic permeability, remains fixed in space, and a continuous rotation is therefore set up. It is upon this action that M. Menges' generator is based, the field being, of course, immensely more powerful.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

(*Continued from page 260.*)

CHAPTER VII.—*Simple Tests with Indicators.*

73. Before leaving the subject of current indicators, or detectors, and proceeding to the consideration of current measurers, or galvanometers, it will be the attempt in this chapter to describe the methods of using the former instruments for some ordinary simple tests.

The most frequent use to which a detector is put is to ascertain whether a given circuit is metallically continuous, or, in other words, to test the circuit "for continuity."

(*a.*) *Tests for Continuity.*—In all electrical circuits containing apparatus in which certain contacts are "made" and "broken" at intervals, or continuous electrical contacts are made through moving parts of apparatus, such as the lever and axle of a switch or key or the carbon rod of an arc lamp, there exists a liability to loss of continuity through these contacts, either owing to their not being sufficiently clean, wearing away, oxidation, insufficient pressure between the surfaces of contact, or gradual fusing of the contact points as the result of sparking. Platinum is used for contacts, as it is a hard metal, and does not oxidise. As regards pressure between contacts a wheel or rolling contact is not so reliable as a rubbing contact where it is required to make continuous connection with a moving part. Switches for altering battery power or changing the connections of circuits are not considered reliable if they make more than three contacts at the same time. They are sometimes provided with screws for adjusting the pressure after the switch lever is in position, or, as in Hedges' form of switches for large currents, small independent springs exert a continual pressure between the lever and the contact. A later device still to ensure never-failing contact in a lighting circuit is to make the lever actually cut into the contact brass blocks, which latter are made of such a form that the wear can easily be taken up.

Where the pressure exerted is manual, as in the case of signalling keys in telegraphy, the operator easily acquires the difference in pressure requisite for working a long or short cable.

If sparking occurs between two contacts, such as would be the case if the contacts were required to effect intermittent short-circuit across the terminals of an electro-magnet through which a current was passing, or "make" and "break" its circuit, a high resistance, say of carbon connected permanently between the contacts, offers a path for the "extra current" from the electro-magnet, reducing the sparking and preserving the contact surfaces. It is seldom that wires connecting together parts of apparatus or leading wires running between different rooms of a telegraph or telephone office actually break, though they may do so in some cases, as for instance, if exposed to the corrosive effect of acid at any point, or if led round a sharp corner and subjected to strain or abrasion. But it is not at all an unfrequent occurrence for a contact to fail between a wire and the terminal to which it is screwed. Either the terminal is too large for the wire and does not properly grip it, or the wire has been bent in a loop round the terminal the wrong way—that is, in the direction *opposite* to that in which the screw turns, so that any extra tightening of the screw may force the wire out altogether; or the wire may be attached to a battery terminal which has become corroded and surrounded with crystals due to "creeping" of the battery liquid, in which case a bad contact would be made.

74. It sometimes happens that through failure of some contact in his own *receiving* circuit connections, the operator at one end of a telegraph line spends a long time in "calling up" the station at the other end, which, while answering all the "calls," is quite unable to speak to the station calling.

It is therefore one of the first considerations to look well after the receiving-circuit connections if no reply to a call is immediately forthcoming.

To illustrate this, a very simple example will now be taken of a fault of this kind occurring, say, in the receiving

Digitized by Google

circuit of a single-current Morse signalling instrument. The illustration (Fig. 34) represents the apparatus usually mounted and connected together, and consists of a Morse ink-writer, M, sending key K, for transmitting signals by hand, line detector D (which can be short-circuited when not required by plugging *p* in *s*), and four terminals marked earth, line, copper, and zinc. The sending battery is, of course, external to the instrument, and is connected to terminals C Z. The sending key is a brass lever, movable about the centre *t*. The lever is generally electrically connected to *t* by a short flexible spiral of wire, since a failure of contact may occur at the axle about which the lever turns when manipulated. The back contact *b* is always closed when the key is at rest, the lever being kept in this position by the adjustable spring at the back. In this position it will be seen that, if there is no fault in the circuit, a current arriving from the line to the terminal L has a path open to it through the detector D, from *t* to *b* of the key, and through the electromagnet of M, to the terminal E, and thence to earth, completing the circuit back through the earth to the sending battery at the distant station. If there is some fault or break in this circuit, the detector already attached to the instrument can be readily used for localising it.

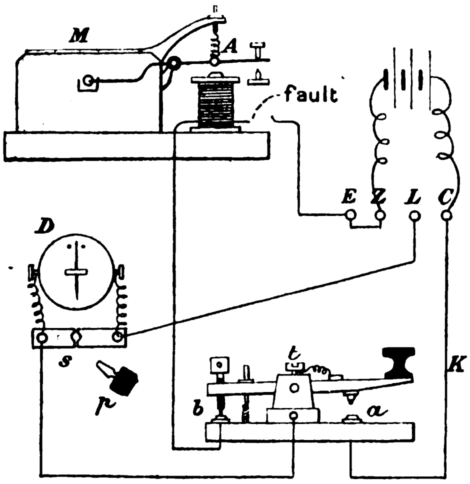


FIG. 34.

We will suppose the sending circuit to be all right. If this is not known it can easily be tried by connecting a wire between E and L, which short-circuits the instrument, and then if D is deflected every time the key is pressed it proves the circuit and the battery to be all right. Now disconnect the wire between E and L, and test the receiving circuit by taking the battery wire off C and putting it on to L, which connects the battery direct to the receiving circuit. No deflection will be observed on D, as there is some fault in this circuit. Disconnect the other battery wire from Z, and hold it in the hand so as to be able to connect it to different points in the circuit. We know the circuit is right from L to the key at *t* from the previous test, so that touching the end of the wire held in the hand on the metal at *t* we should get a deflection on D. Now, suppose that a deflection is observed when the end of the wire is touched at the lower contact at *b*; this shows that the back contact of the key is good. Also let deflections be noticed on touching the wire to the beginning and end of the electro-magnet coil of M, showing that the connection from *b* to the coil and the coil itself are all right. There is only one place now where the fault can be, which is between the coil and the terminal E, and on closely examining this connection underneath the instrument the break would be found, probably caused by the drawer containing the paper slip having chafed against the spiral of thin wire from the coil.

What has taken some time to describe here is really only the work of a few seconds, and it is quite a simple operation with practice and a knowledge of the circuits to speedily localise in this manner any fault in any set of connections, however complicated.

(*To be continued.*)

REVIEWS.

A Course of Lectures on Electricity, delivered before the Society of Arts, by GEORGE FORBES, M.A., F.R.S., &c. (London: Longmans, Green and Co., 1888.)

This is a reprint of the Cantor Lectures, delivered by Prof. G. Forbes in the spring of 1886, with the addition of a lecture on dynamo-electric machinery originally delivered at the Electrical Exhibition in Philadelphia in 1884 at the request of the Franklin Institute. The Cantor Lectures were fully reported in this journal at the time of delivery, but the present reissue has had the advantage of undergoing a further revision on the part of the author, and is also very fully and very well illustrated throughout. "The lectures," says the preface, "were primarily intended for an intelligent audience, ignorant of electrical science but anxious to obtain sufficient knowledge of the subject to be able to follow the progress now being made in the science." It will therefore be seen that this book in its present form appeals to a very wide circle of readers, and one for whom provision of this character has not hitherto been made by anyone nearly so well qualified for the task as Prof. Forbes. It is sufficient to add that the intention expressed by the preface will be found to have been admirably fulfilled.

SERIES GLOW LAMPS.*

BY WILLIAM SIEMENS.

The great obstacle which has hitherto prevented this system from coming into more extended use has lain in the manufacture of the lamp itself, for it is no easy task to make a good lamp with a filament large enough to take a current of some ten or more amperes.

One difficulty arises from the necessity for all the lamps to take the same current. An ordinary modern Edison lamp for parallel, running at 3·2 watts per candle-power, increases in resistance about 5 per cent. in an 800-hours' run; the old pattern used to increase about 13 per cent. in the same time. This increase, as has often been pointed out, has a preservative effect in a parallel system, but a destructive one when all the lamps are run in series, for in the latter case the same current has to pass through an increasing resistance, the work done in the lamp gets greater and greater, and the temperature of the filament higher and higher. A carbon, therefore, that is sufficiently good for parallel work would not do for lamps which have to run in series; but one must be used which does not increase so much in resistance when running. It may here be noted that series lamps, being almost necessarily of high candle-power, are mostly used for outdoor work, and therefore when competing with gas do not have any advantage over that rival on hygienic grounds, as is the case with parallel lamps in house work. It is therefore necessary that a series lamp should be more efficient than its congener if it is to stand an equal chance with it in respect to gas.

The firm of Siemens and Halske have been at work on the subject for some years, and are now making 11-ampere series lamps of 50 and 100 candle-power, with 10 and 20 volts respectively; an efficiency of 2·2 watts per candle-power, or 30 per cent. better than their parallel 16 candle-power lamps which require from 3 to 3·2 watts.

Although the carbon used is formed much in the same way as gas retort carbon, viz., by the dissociation of hydrocarbons, yet it possesses physical properties in which it differs not only from retort but also from all other kinds of carbon.

Its specific resistance is 689 microhms, that of a sample of bamboo carbon (unflashed) being 6,014. (Tabulated results of determinations of temperature coefficient of three Siemens and two unflashed bamboo carbons are here given for temperatures up to 200deg. C. The Siemens coefficient falls from about ·16 per cent. at 16deg. to ·12 per cent. at 200deg., while the Edison rises from ·029 to ·036 in one case and remains at ·026 throughout in the other.) The resistances of both carbons reached a minimum at a white heat when the total diminution of resistance was 55 per cent. for the Siemens and 45 for the bamboo. The specific gravities were 2·01 and 1·58 respectively.

All the above properties show the value. of this carbon for the purpose required, and after a 500-hours' run the resistance of a lamp was found to have hardly perceptibly increased; and the efficiency had fallen from 2·25 watts per candle-power to 2·35.

Besides the carbon other difficulties have to be encountered in large current lamps, in the matter of making good connection to the carbon and of fusing the platinum wires into the glass.

* Abstract of a paper read before the Electrotechnische Verein, Berlin, 27th December, 1887.

Digitized by Google

The usual horseshoe filament (or, in this case, rather horseshoe rod) is found to be the best in this as in the ordinary parallel lamp, although, at first sight, a straight rod with leading-in wires opposite to one another would appear preferable. The wires are very long and thick, and naturally very difficult to seal in air-tight. The ends of the filament are considerably enlarged and electroplated (with nickel) into metal cups, which in turn are soldered on to the platinum wires.

The author then describes a rather complicated mechanical device for short-circuiting a lamp when it breaks.

The alternating has a great advantage over the direct machine for series running, owing to the automatic regulation caused by the self-induction of the armature. A Siemens alternating running at 1,700 volts, with 11-ampere glow lamps of 60 and 100 candle-power, caused no injurious alteration in the remainder when one-third of them were suddenly short-circuited, a greater alteration than would ever occur in practice.

The author goes at considerable length into the *pros* and *cons* of series running as compared to parallel. The chief argument brought forward in favour of the former system arises from the fact that the distance from the central station at which lamps may be economically run is much increased. Where it is *necessary* that this distance should be very great the series system should undoubtedly be employed. The distance for parallel working is, however, no small one. For example, at Eberfeldt the author's firm have installed a central station on the three-wire system for 10,000 16 candle-power lamps, feeding a district some 2½ kilometres (1·5 mile) across.

He is of opinion that the series system has but a limited field, being practically only suitable for streets, tunnels, stations, mills, &c., where lights of 50 and 100 candle-power are wanted, and for which use it has a great advantage over the arc lamps in only requiring attention once in 800 hours instead of once in 8.

The author strongly attacks the Bernstein system of house-to-house lighting by series lamps, on the ground that the lamps cannot be satisfactorily made of sufficiently low candle-power, that they are three times as expensive as parallel ones, that there is considerable danger to life, and lastly, that it is no cheaper, if indeed as cheap, as parallel installations on the three-wire system. The cost for mains he admits is only one-third or one-half of that for parallel running, which he puts at 30s. per 16 candle-power lamp; but against this saving there is the cost of the automatic short-circuiting arrangements, and these, he says, will cost as much as to lay down the mains for the whole district on the three-wire system. Besides, the cost for mains is, after all, only a portion of the total expenses, and the depreciation on them is not nearly so heavy as on the dynamos and other plant.

The rest of the paper and the whole of the discussion deal with the effects of high potentials on the human body, and of this we hope to give an abstract in a future issue.

ELECTRIC LIGHTING OF TRAINS.

At the recent meeting of the International Railway Congress the following report was presented by the management of the Belgian State lines upon the subject of the electric lighting of trains :—

The different sources of electricity which have been tried are: (1) Primary batteries; (2) accumulators, or secondary batteries, placed (*a*) in the van or baggage car, (*b*) in each car, so as to render the lighting independent; (3) a dynamo electric machine connected to one of the axles with accumulators to keep up the lighting when the train is at rest; (4) a dynamo operated by a special motor placed on the locomotive or the baggage car, and supplied with steam from the engine or a special boiler.

Electric light presents the advantages of brilliancy, whiteness, steadiness, ease and convenience of management. Some of the difficulties are: Cutting up trains, if the supply be from a single source for the whole train, cuts off the cars from the light. The apparatus is usually complicated or delicate. The cost is not yet certainly known. If accumulators are used, the question of cost, &c., becomes still more complicated. To increase the life of the lamps it has been proposed to shut off part of the light when the full power was not required. The introduction of compound-wound dynamos has, however, obviated some of the difficulties formerly experienced in train lighting.

(1.) Primary Batteries.—Primary batteries cannot generally produce electricity economically, but it has been attempted to use such batteries for train lighting on the Midland and South-Eastern. On the Midland each car has six 5 candle-power lamps; there were 15 Holmes and Burke elements put together in series of five elements each, and the electromotive force of each element was 1·85 volt, and its internal resistance 1-40th of an ohm. The light lasted ten hours without renewing the battery, but it was necessary to amalgamate the zincs twice a week. The solution around the zincs was a mixture of one part sulphuric acid and 12 of water. Around the carbon element was some kind of salt, precisely what is not stated. Similar results were obtained on the Great Northern, the South-Eastern, and the London and South-Western. The cost is unknown, but as the battery has not come into extensive use it is to be presumed that it is too high.

Inventors are still coming to the front with primary batteries, which are announced to be capable of producing electricity for almost nothing; but trials have demonstrated very clearly that to produce electricity by the consumption of zinc, or some other equally high-priced metal, is, at least, ten times more expensive than to get it from dynamo machines. The International Sleeping Car Company is running a car daily between Brussels and Paris lighted by 14 electric lamps said to be of 10 candle-power, but really giving only seven or eight. The experiments are under the charge of M. L. Desruelles, an engineer of Paris. There are 45 elements, connected 15 in series and three in quantity. The zinc electrode is immersed in a solution of bisulphate of mercury, and the carbon in a mixture of bichromate of soda, sulphuric acid, and nitric acid. A charge of liquid lasts during four trips of seven hours each, and the zincs must be replaced by new ones about every sixteenth trip. Primary batteries have the advantage of being easily placed under each car, and susceptible of making the light of each car independent.

(2.) Secondary Batteries.—The London and Brighton made a prolonged trial of lighting by accumulators, taking them out for charging. It considers that the labour required for this is an obstacle to their practical and economical use. It also necessitates the erection of a sufficient number of charging stations, or the transportation of the batteries to and from the place of charging. The placing of accumulators under each car would, as in the case of primary batteries, render the lighting of each car entirely independent. The Paris and Orleans also made some experiments with primary batteries, arranged (1) to charge the accumulators alone without feeding the lamps; (2) to feed the lamps from the accumulators only; (3) to charge the accumulators and feed the lamps at the same time. The accumulators were of the Faure type, and a sufficient number were carried to light the lamps for twenty or thirty hours. They were placed under the seats, and the weight required was 450lb. to 650lb. per car. Two Swan lamps of 10 candle-power were used in each compartment. Lighting by means of accumulators can, of course, only be done with considerable loss, but this system seems to have the best chance of success, although these particular experiments did not succeed well, owing to the destruction of the plates and leakage of the boxes, and the difficulty of maintenance. Improvements in the accumulators may improve the conditions and reduce the cost.

(3.) Dynamos Connected to a Car Axle, with Accumulators as a Reserve.—The great difficulty of obtaining a regular current from the dynamo connected to a car axle makes the employment of accumulators as a regulator very important. They are necessary also to maintain the lamps lighted when the train stops at a station or elsewhere. Automatic appliances must be provided which shall cut off the current from the dynamo when it falls below a certain speed in order that the batteries may not discharge themselves through it. The dynamo must either always turn the same way or means must be provided for always delivering the current to the batteries in the same direction. There are many devices for this purpose. Many railroads have tried this method. The transmission from the axle to the dynamo has been accomplished by belts, gearing, friction cones, worms, &c. Magnetic transmission has also been tried. None of these methods have been satisfactory, though the friction method gives the best results. A novel method has also been used by Preece and James, where a system of excentrics on the axles compressed air, which was afterwards used in Brotherhood motors. The accumulators, instead of being in the car with the dynamo, are sometimes placed in every car in the train, but this increases the complication, though the cars are thus independent of each other, so that the cutting or breaking apart of the train does not extinguish the light. Besides the loss of electricity by the use of accumulators this method requires a special car and a man to manage the apparatus, which greatly increases the expense. The London and Brighton, however, after a prolonged trial of accumulators charged at one end of the line, has now abandoned that system, and uses a dynamo driven by one of the axles for charging accumulators.

(4.) Special Motor Operating a Dynamo.—This scheme introduces more objectionable features than the preceding. The principal disadvantages are: (1) The extra consumption of steam, which for a small motor is usually very high; (2) the care of the apparatus would be of necessity given to the engineer, who already has enough to do; (3) every time the engine was detached from the train the lamps would be extinguished; (4) a breaking apart of the train would leave the rear portion in darkness; (5) if the motor is placed in a car behind the engine it requires a special attendant

Digitized by Google

for this car to go with the train. This apparatus makes a considerable addition to the dead load of the train, and the cost of attendance is larger; (6) to render the lighting perfectly satisfactory accumulators must be used to regulate the light and maintain it while the engine is detached from the train. The London and Brighton is lighting its "Pullman Limited Express" in this way. In the van is a small Brush dynamo operated by the rear axle by means of belts. There are 86 lamps of 16 candle-power each and a battery of 24 accumulators attached to this dynamo. In the daytime the dynamo charges the accumulators and the lamps are used only when passing through tunnels. The expense of lighting this train is not given, but it is said to be too costly for ordinary trains.

The management of the Royal railroads at Frankfort-on-the-Main has experimented with electric lighting. Three cars were fitted with lamps, and a dynamo and 26 accumulators were in the van, the dynamo being operated from one of the axles. The dynamo and accumulators weighed about 1,320lb., and cost $625. The lamps in each car cost about $20. The lighting costs two cents per lamp per hour, while gas-lighting on the State roads of Belgium costs exactly 0·28 cent per burner per hour.

In 1884 the Metropolitan District tried lighting by a dynamo and special motor. The total weight was over three tons, including water and fuel. A Siemens dynamo feeds 52 lamps of 18 candle-power each for eight hours per day. Three cubic feet of water were evaporated at a pressure of 185lbs. per square inch. Only 4½ horse-power appeared as electric work in the lamps and conductors, the rest being absorbed by friction, &c. This experiment was not satisfactory, as the boiler fouled very quickly, and had to be taken to the shop for cleaning. In the experiments made on the Wurtemburg railroads in 1886, the dynamo was run by a belt from a pulley on one of the axles of the baggage car. An electric regulator was used, and a number of accumulators sufficient to keep the lamps lighted for five hours were placed in each car. The accumulators were put in circuit to be charged only when the speed of the train reached 20 miles an hour. When the current became too great it was automatically interrupted. The current was divided between the lamps and the accumulators, and when the train stopped, these latter furnished the current for the lamps until the train was again running at 20 miles per hour. The dynamo worked whether the train went forwards or backwards, because the brushes adjusted themselves automatically to the direction of the train. It appears that the accumulators worked satisfactorily. The lamps were of the Bernstein system, and the accumulators of the Khotinsky type. An express train running between Vienna and Trieste was fitted with a dynamo and Calo accumulators, 28 in number, weighing 37lb. each. They were sufficient for lighting 40 lamps of eight candle-power each during the stops of the train. The dynamo at 1,200 revolutions gave 100 volts and 50 amperes. It had an automatic compensating apparatus for regulating the flow of the current into the accumulators or the lamps, or both at once. The lighting was for about 15 hours per day. The trials appear to have been satisfactory. A train running between Munich and Starnberg was lighted by a dynamo run by an Abraham four-cylinder engine. The light was very unsteady. In England a similar experience was had with a Willans motor and a dynamo. A mixed system devised by M. Donato Tommasi burned gas during the stops of the train, electricity furnishing the light when the train was in motion. The electric current partially shut off the gas. This does not appear to be a practical system. The trains while passing through the tunnels on the Glasgow underground are lighted by electricity. A third rail laid between the other two is carefully insulated and connected to one pole of a dynamo, the other pole of which went to earth; the two outside rails of the track are also grounded. Rollers under every car make contact with the third rail and convey the current to Swan lamps in the cars, the current returning to the dynamo through the wheels and the earth. The lamps were thus automatically lighted on entering the tunnel and extinguished on leaving it.

Electric headlights have been used between Munich and Tolz, Strasbourg and Wissenbourg, on the Northern of France, and on the State Railway of Austria. The Northern of France rejected the system not because of its working badly, but on account of the expense. No information has been obtained regarding the experiments in Austria. Among the chief difficulties to be overcome was the jarring of the locomotive. It is also difficult to keep the arc in the focus of the reflector. Another serious annoyance is the placing of an electric machine upon the locomotive.

All the foregoing trials demonstrate the possibility of lighting trains by electricity, but the question of the most practical system is not yet solved. All the systems of electric lighting of trains not known would at least double the regular cost for maintenance, beside the first cost of the apparatus, which should also be considered. In the present state of the question electrical lighting appears too expensive except in special cases where its use is justified as a luxury, and the expense is only a question of secondary importance.

MEETINGS OF SCIENTIFIC SOCIETIES.

(Week ending Friday, 3rd February.)

TO-NIGHT (FRIDAY), January 27th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Paper to be read, "Pumping Machinery in the Fenland and by the Trentside." By Mr. LAWRENCE GIBBS, Stud I.C.E.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Indian Section. "The Public Health in India." By Mr. Justice CUNNINGHAM, of the High Court of Judicature, Calcutta. Sir DOUGLAS GALTON, K.C B., F.R.S., will preside.

PHYSICAL SOCIETY OF GLASGOW UNIVERSITY.

Paper on "The Electrolysis of Copper in Standardising Electrical Instruments." By Mr. A. W. MEIKLE.

ROYAL INSTITUTION.

9 p.m. Lecture, "The Exploration of Masăi Land." By Mr. JOSEPH THOMPSON, F.R.G.S.

SATURDAY, January 28th.

ROYAL INSTITUTION.

Lecture, "Experimental Optics." By Lord RAYLEIGH, M.A., &c.

PHYSICAL SOCIETY.

3 p.m. "The Effect of Magnetisation on the Thermo-Electrical Properties of Bismuth." By Mr. HERBERT TOMLINSON. "The Influence of Magnetism and Temperature on the Electrical Resistance of Bismuth and its Alloys with Lead and Tin." By Mr. E. VAN AUBEL. "On a Water-Dropping Influence Machine, and on the Price of the Factor of Safety in Lightning Rods." By Professor S. P. THOMPSON.

MONDAY, January 30th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture II. The first of a series of four Lectures on "Yeast, its Morphology and Culture." By Mr. A. GORDON SALOMON.

TUESDAY, January 31st.

SOCIETY OF ARTS.

8 p.m. Applied Art Section. "The Monumental Use of Bronze." By Mr. J. STARKIE GARDNER, F.G.S. Mr. J. POYNTER, R.A., will preside.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed, "The Erection of the 'Jubilee' Bridge, carrying the East Indian Railway over the River Hooghly, at Hooghly." By Sir BRADFORD LESLIE, K.C.I.E, M.Inst.C.E. Paper to be read, time permitting, "The Alexandra Dock, Hull." By Mr. A. C. HURTZIG, M.Inst.C.E.

ROYAL INSTITUTION.

3 p.m. Lecture, "Before and After Darwin." By Mr. GEO. J. ROMANES, M.A.

WEDNESDAY, February 1st.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "The Functions of the Middleman in Relation to Labour." By D. F. SCHLOSS.

THURSDAY, February 2nd.

ROYAL SOCIETY.

4:30 p.m. Ordinary Meeting.

ROYAL INSTITUTION.

3 p.m. Lecture, "Art Education." By Mr. HERBERT HERKOMER, M.A., A.R.A.

CHEMICAL SOCIETY.

8 p.m. Meeting.

SOCIETY OF ARTS.

8 p.m. The first of a series of three Lectures on "Etching and Mezzotint Engraving." By Prof. H. HERKOMER, A.R.A.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Meeting.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

Students' Meeting. Discussion on the recent Paper by Prof. FLEMING, Mr. GIMINGHAM, and Profs. AYRTON and PERRY, will be opened by Mr. C. G. LAMB, B.Sc.

FRIDAY, February 3rd.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Meeting.

ROYAL INSTITUTION.

9 p.m. Discourse on "Ancient Microscopes." By Mr. FRANK CRISP, LL.B., B.A., M.R.I., V.P. and Treas. Linn. Soc., Sec. R.M.S.

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not ater than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

THE ELECTRICIANS' DIRECTORY.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY IS NOW READY.

NOW READY.

Volume XIX. of "The Electrician," strongly bound in cloth, is NOW READY, price Ten Shillings and Sixpence.

Cases for binding "The Electrician," price Two Shillings, Now Ready.

THE WORLD'S ELECTRIC INDUSTRY.

During the past year, which was the year of Jubilee for the Electric Telegraph, many attempts were made to estimate the material, social and political advantages derived from the adoption of electricity as the world's swift messenger. The subject was so vast, the consequences so far-reaching, and so intermingled with other active agencies, equally progressive, during the same period, that little more than bold but magnificently vague generalities could be arrived at, and we were left with the comforting but intangible reflection that the electric telegraph had done such wonders nobody was able to estimate them. Mr. GRAVES has carried us a little nearer to a practical realisation of our indebtedness, and, what is more, has indicated the road we must take to estimate its fulness. In his presidential address to the members of the Society of Telegraph-Engineers and Electricians Mr. GRAVES undertook the initial but very formidable task of enlightening us as to the actual extent of the electric industries of the world, how many people are engaged in it, how many live upon it, and how many are industrially more or less concerned with it. In such a survey the electric telegraph still takes a prominent, but not the preponderating, part it occupied at the period from which Mr. GRAVES dates his connection with it. Other industries of vast dimensions have sprung up which owe their origin and development to electricity, and according to his estimate almost as many people are occupied in electric lighting, electro-plating, and kindred manufactures dependent upon them, as in working the telegraphs. Aggregating the whole field of electrical industry known to us, and estimating the number of hands they employ on the basis of figures obtained from reliable sources in this country, Mr. GRAVES has placed before us for the first time some tolerably safe calculations on this interesting subject, and the results are very striking.

Beginning with the fact that in the United Kingdom there are 229,000 miles, or thereabouts, of public telegraph wires, employing 23,868 persons, Mr. GRAVES computes that on the world's telegraph lines, approximately amounting to 1,800,000 miles, not including submarine cables, a total number of 179,748 persons find their occupation exclusively in telegraphic signalling operations. From this computation are

Digitized by Google

excluded persons who only partially are so employed, as, for instance, on railways and in post offices where telegraphy is only a subsidiary part of their duties, and who, if they had been included in the basis of calculation, as indeed they partly ought to be, the grand total would have been immensely swollen. But taking the basis of exclusive occupation, and proceeding in the same way with cable telegraphs and telephones, Mr. GRAVES sets down the *employés* of the former at 6,000, almost exclusively British, and of the latter at 30,000, covering, of course, the whole world. This gives us a grand total of 216,000 operators, a number which is increasing every day with great rapidity all over the world with the spread of the telegraph and the telephone and the laying of fresh cables. Mr. GRAVES describes himself as a mere stander-by, who has simply watched the progress of telegraphy for the space of thirty-six years. No one who knows him would accept this modest estimate of the part he has played in the history of the industry with which his name is so closely identified; but the most presumptuous of men might join in his exclamation, "I am struck with astonishment," when he recalls the smallness of its beginnings, and the littleness of its knowledge in 1852, compared with what the telegraph has grown to be to-day.

By a similar method of computation the figures relating to the other electric industries are arrived at. But Mr. GRAVES very justly pointed out that at the time above referred to the working of the telegraph was, broadly speaking, "the sole demonstration of electricity that could be commercially cultivated." Since then new fields for its application have been opened up which were then undreamed of, but largely owing to the success attending its adaptation to the needs of the community as a signalling agent. The mind of the student was set free, and the spirit of unshackled inquiry soon discovered fresh work on which this natural force could be usefully and profitably employed. So fruitful have been these discoveries that in one English manufacturing town alone there are 5,000 hands engaged in electro-plating and electro-gilding processes; and in this regard Sheffield, the town referred to, is probably not far ahead of Birmingham. But these and their allied industries, dependent for their success on the discoveries of electrical science, are so widely spread that it is impossible to state, except conjecturally, how many persons are engaged in them, but the total for the whole industrial world must be very large indeed. In the manufacture of submarine cables, and of insulated wire, an industry which is far more concentrated, the *employés* are ascertainable, and average about 5,000. For the electric lighting industry Mr. GRAVES has assigned a gross total of not fewer than 100,000 persons, on the basis that at least 5,000 are employed upon it in our own country. High as his estimate may appear at first we feel sure that, like those for the rest of the classified electric industries, Mr. GRAVES has understated rather than overstated the facts; and if this is the case the rapidity with which this quite new employment has grown is at once remarkable and encouraging.

Putting all these estimates together we arrive at some general conclusions like the following:—Adding to the 216,000 persons employed in electrical signalling the 105,000 engaged in the supply of cables and electric lighting, we have a total of 321,000. But this is very far indeed from representing the actual total of persons whose living directly depends upon electric industry, although not immediately connected with it. Of these it may suffice to mention the wire drawers, iron workers, copper smelters, timber growers and their workmen, creosoters, insulator makers, brass workers, engine builders, boiler makers, glass blowers, mechanicians, carbon manufacturers and the like, whose total number Mr. GRAVES—who ought to be a trustworthy authority on the extent of these subsidiary industries—estimates at about equal to that of the persons distinctly classified in electrical callings. In the United Kingdom, according to this, about 100,000 persons depend for their livelihood upon industries which, but for the practical utilisation of electricity, would have no existence; and reckoning only three for the family, instead of five, or four and a-half, where adults only are employed, these industries provide support for 300,000 persons. Multiplying this by the proportion which the electric industries of this country bear to the rest of the world, there must be, Mr. GRAVES concludes, at least 5,000,000 of people who would have to look to other means of subsistence "if electricity and its commercial applications had not been made known to man."

Calculations such as these do not bring us much nearer to the measure of those advantages to which we adverted in the opening sentences of this article. But they are eminently practical, and they go a great way towards rendering the more fanciful speculations superfluous. We may rest content with the substantial blessings enumerated by the President of the Society of Telegraph-Engineers and Electricians, who naturally prefers to emphasise the ascertainable benefits conferred by the practice of his profession, rather than to balance the evil and the good which social and political life may extract from it. In one other way the new president showed the practical bent of his mind. Although all his working life has been devoted to the telegraph service, he frankly confesses that telegraph engineering has ceased to occupy its once undisputed pre-eminence in the field of applied electricity. Other branches of electric industry are now running it closely, and he is magnanimous enough to admit that the society with which he has been so long associated as a telegraph-engineer, and over which he now presides, ought to mould itself to the times, and change its title to the more comprehensive one of ELECTRICAL ENGINEERS. Coming from a representative of the most powerful element in the society, this announcement, which was well received by the members who heard it, can hardly fail to be carried out during Mr. GRAVES' term of office.

CENTRAL STATION INDICATING INSTRUMENTS OF THE EDISON COMPANY.*

(Continued from page 268.)

The Edison three-wire system, as is well known, is made up of two multiple arc systems connected in series, with the wire, which is common to both, connected to the source of current in such a way as to give to each all the advantages of a simple multiple arc system. These two systems, known as the two sides of the three-wire system, are intimately associated, the same current being used in both. Nevertheless, as far as regulation is concerned, they are almost absolutely independent. The two sides have separate indicating and regulating apparatus, and the regulation of each side is performed without any reference to the other. As most consumers get half their lamps from each side, it is very necessary that the pressure on both sides be the same; otherwise a difference between the brightness of the lamps on the two sides will be noticed.

It is the function of the balance indicator to show at all times whether or not the pressures on the two sides are the same.

In connection with the pressure indicator there is employed a galvanometer which in the three-wire system acts as a balance indicator, and thus indicates whether the pressure on both sides of the system is the same.

Its function is shown in the diagram, Fig. 6, which shows a pair of pressure indicators connected to the pressure wires from a feeder end on the three-wire system. R R are two equal high resistances,

* From the New York *Electrical World*.

Digitized by Google

and B the galvanometer; R, R and B are connected as shown directly to the three-wire circuit. The point C is electrically midway between the + and − wires, and its potential is half way between the potentials of the + and − wires. When the pressures on the two sides at this point are the same, the potential of C′ is also midway between the potentials of the + and − wires. Then the points C and C′ are at the same potential, and no current flows through B, and it remains at zero. If, however, the pressures on the two sides are not the same, then the potential of C′ is not midway between the potentials of the + and − wires, and C and C′ are not at the same potential. A current then flows in B which deflects the needle, and the direction of deflection shows which side is highest.

On a three-wire system using the comparative method of indicating pressures, which will be described later on, only two absolute pressure indicators are used, one on each side of the system. If one of these changes, the pressure on all that side changes, as the comparative indicators simply copy the pressure kept by this indicator. If, however, there is a balance indicator connected around the two indicators, any change in either one of them is immediately shown and can be remedied. In the diagram S S indicates lamp sockets. If at any time it is necessary to take down one of the two pressure

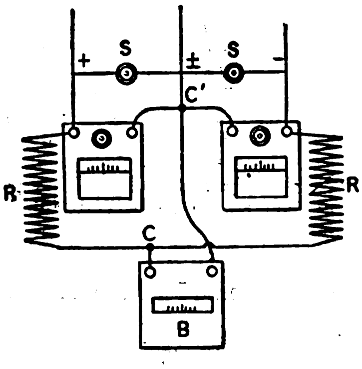

Fig. 6.

indicators, the lamp from this indicator can be screwed in the socket above the indicator taken out. The pressures can then be regulated by one pressure indicator and the balance indicator, the one pressure indicator holding the desired pressure on one side, and the balance indicator showing when it is the same on the other side. The galvanometer used for the balance indicator is also used in throwing dynamos in circuit.

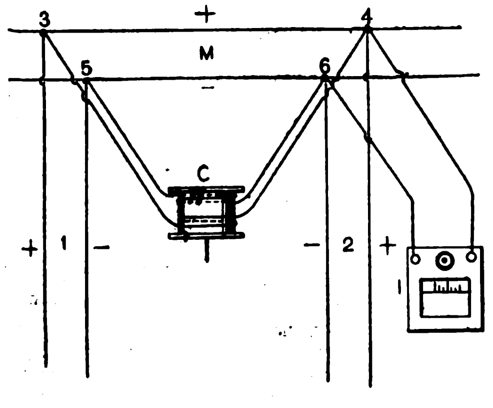

Fig. 7.

In distributing currents at constant E.M.F. it is necessary to maintain the same pressure at the ends of all the feeders, and this may be accomplished by connecting a pressure indicator to each side of each feeder end, and regulating each point by reference to these pressure indicators. This method, in a three-wire system, evidently requires twice as many pressure indicators as there are feeders, each one of which has to be kept in adjustment. The same result, however, may be accomplished by maintaining the desired pressure at the end of one feeder by reference to pressure indicators, and at the other feeder ends by reference to comparative indicators. The advantage of this method is that the two pressure indicators only need to be kept in adjustment; the comparative indicators being once set up require practically no attention.

Fig. 7 is a diagram showing the principle upon which this indicator operates. In the diagram M is the distributing circuit, and 1 and 2 are feeding circuits. At the point where feeding circuit No. 2 joins the distributing circuit, a pressure indicator, I, is connected, by reference to which the pressure at that point is kept at the desired standard. C is a differential galvanometer, or "comparative indicator," connected as shown, one coil being joined to points 3 and 4, and the other to 5 and 6. If now the points 3 and 4 be at the same potential and the points 5 and 6 be also at the same potential, then the difference of potentials or pressures at the end of feeder No. 1 is the same as at the end of feeder No. 2. No current will flow from 3 to 4, nor from 5 to 6, and the galvanometer C will remain at zero. Again, if the point 5 be at the same potential as the point 6, but the point 3 be at a different potential from the point 4, there will then be a current in the coil connected between 3 and 4, and the galvanometer will show a deflection one way or the other, depending on whether point 3 is higher or lower than the point 4. Under these conditions, C would give a deflection, as the pressure at the end of feeder No. 1 is not the same as at the end of feeder No. 2. If, now, the + wire of feeder No. 1 be adjusted until 3 is at the same potential as 4, C will come to zero, for then the pressures at ends of No. 1 and No. 2 are equal. Instead of adjusting the + wire of feeder No. 1, the − wire of feeder No. 1 may be adjusted to bring the galvanometer C to zero. When C is brought to zero in this way the point 5 is made just as much higher or lower than 6 as 3 is higher or lower than 4. There are then currents in both coils of the galvanometer C, but they will be equal and balance each other, and C will remain on zero, as it should, since the difference of potentials or pressure at the two feeder ends is the same.

The diagram, Fig. 8, shows the manner in which the comparative indicator is applied. There are here shown the pressure wires from three feeders—No. 1, the standard feeder, and two others. From each feeder a set of iron pressure wires is run; these are marked I I, and the points on the comparative indicators to which they are connected are also marked I. From the end of feeder No. 1 an extra set of pressure wires is run; these are of copper wire and run to all the comparative instruments, as shown, being connected

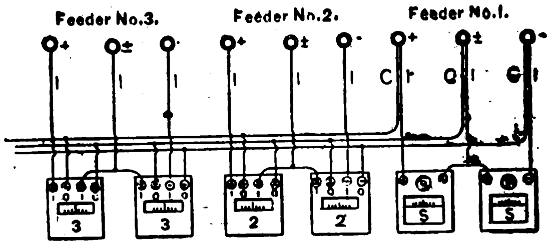

Fig. 8.

to the point marked C. This is the manner in which the comparative instruments are connected in all three-wire systems, except that in some systems only one set of pressure wires is used on No. 1 feeder. When connected as shown, the pressure at the ends of feeders Nos. 2 and 3 is compared with the pressure at end of feeder No. 1, and when all the comparative indicators are at zero the pressure at the ends of all three feeders is the same.

Portable Voltmeter.

All the instruments thus far described are designed to remain permanently in position, but it is frequently desirable to measure the potential at various points in a circuit, since the indicators at the station give the pressure at the feeder ends only. For this purpose the voltmeter, illustrated in Fig. 9, is employed, the engraving showing the instrument removed from its case, in which it can be readily carried about from place to place.

The operation of this instrument is based on the well-known "potentiometer" or "opposition" method of measurement.

The voltmeter contains a small Daniell cell of known constant E.M.F. The E.M.F. of this cell is opposed to the E.M.F. in a part of the voltmeter circuit, and this part can be varied by moving a sliding contact, to which one terminal of the battery is connected, along a resistance forming part of the voltmeter circuit. When the E.M.F. in this part of the voltmeter circuit, around which the battery is connected, is equal to the E.M.F. of the battery circuit, to which it is opposed, no current will flow in the latter, and the galvanometer which is included in it will show no deflection.

The diagram, Fig. 10, shows the circuit connection of the instrument. P P′ are the terminals to which the circuit to be measured is connected; B is the battery of known E.M.F.; G, a galvanometer; C, a contact that is adjustable along a resistance of 20 ohms; S, a switch closing the circuit from P′ through the battery and galvanometer to the contact C. We will assume that the circuit is closed from P′ through B, G, C, part of the 20 ohms, and

Digitized by Google

the 40 ohms back to P′. We will also assume the positive pole of the battery and the positive pole of the circuit to be measured are both connected to P′, and that a current is flowing from P′ to P. Then, in this closed circuit, two electromotive forces exist, which tend to set up currents in opposite directions through battery B and galvanometer G. The battery tends to send a current through G from left to right, and the E.M.F. of the circuit itself tends to make a current pass from P′ to C through G; *i.e.*, from right to left. Hence, when the E.M.F. from P′ to C is equal to the

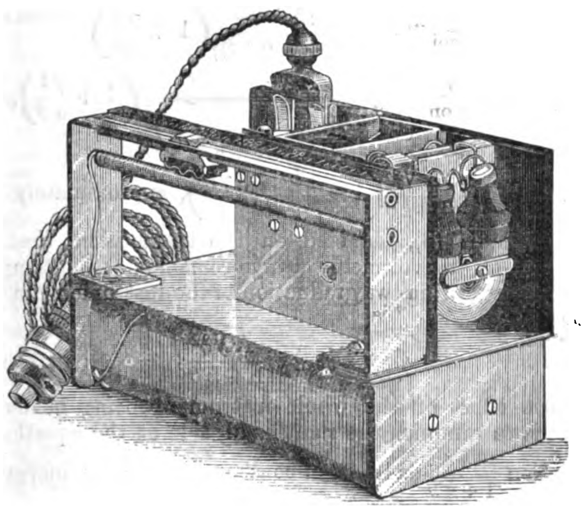

FIG. 9.

E.M.F. of the battery, no current will flow in G, as the two equal E.M.F.'s are opposed to each other, and thus prevent a current from flowing in the galvanometer circuit. Knowing now the E.M.F. of the battery, and the value of the resistances, it is only necessary to know the position of C along the 20 ohms to determine the E.M.F. acting from P′ to P, which is the quantity we wish to measure. The voltmeter is supplied with two standard cells, which can be readily removed for renewal when necessary. By simple

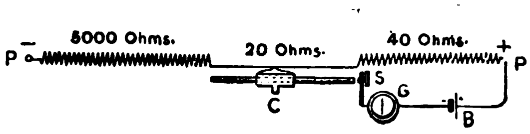

FIG. 10.

sliding connections these may be arranged either in multiple or in series. When the cells are in multiple the pressure necessary to balance the instrument is read directly off the scale in volts; when placed in series the pressure required to balance the instrument is given by doubling the scale reading. The scale usually reads from 90 to 130; with the batteries in series it reads from 180 to 260 volts.

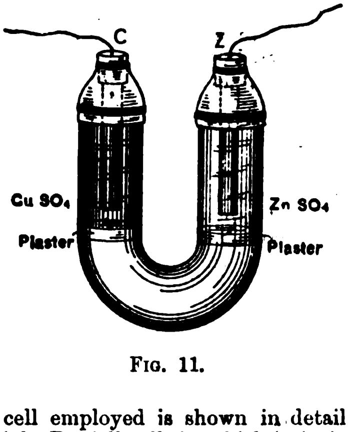

FIG. 11.

The standard cell employed is shown in detail in Fig. 11. It is a portable air-tight Daniell cell, in which it is impossible for the copper sulphate to come in contact with the zinc electrode for three or four months, and during this time the slow progress of the copper sulphate towards the zinc electrode is plainly visible. The cell consists of a V-tube, the bend being filled with a paste. In each leg of this tube is placed respectively a rod of copper and zinc, dipping into the sulphate solution of the same metal.

The blue copper sulphate colours the whole paste as it advances; the line between the blue and white is plainly marked, and, as time passes, the blue reaches the end of the white paste, after which if it goes further, it will reach the zinc electrode. The battery is then removed and a fresh one inserted. In this way all the trouble of cleaning out and refilling batteries is done away with. The ends of the glass U-tube are closed with rubber tubes, one end of which is stretched over each end of the glass tube, and the other end enclosing the electrode. It is impossible for a battery to leak unless the rubber tube slips off the tube or makes an imperfect joint, neither of which is likely to happen. The copper sulphate solution, as it colours the whole paste, combines with it, and the new compound occupies less space than the constituent substances, so that an inward pressure or vacuum is formed which helps to keep the cell tight.

The use of the voltmeter is quite simple. As will be seen in Fig. 9, a plug is inserted between two contacts, and is connected by flexible cords to another plug, which is inserted into the lamp socket at the point it is desired to test the E.M.F. of. The variable resistance is mounted on a spool, and the sliding contact moves along a scale marked to read volts. When, upon the depression of the key beside the galvanometer, the latter shows no deflection the number of volts can be read directly off the scale.

The principal use of the voltmeter is to determine the pressure *at the lamps* in different parts of the circuit. In central stations a constant pressure is maintained at the feeder ends; the voltmeter enables one to determine just what the pressure is at any point of the circuit. Points distant from the feeder ends necessarily have a lower pressure than the latter, and by means of the voltmeter the exact difference can be determined, and if the difference is too great its cause can be looked for and remedied. Another use for the voltmeter is to measure the loss on pressure wires carrying the indicator currents to the central station.

DEVELOPMENT OF THE TELEPHONE IN AUSTRIA.

In 1883 the subscribers to the eight Exchanges of the Telephone Company of Austria (Limited), viz., Prague, Trieste, Lemberg, Graz, Czernowitz, Pilsen, Reichenberg, and Bielitz-Biala, numbered 442, with 40 private lines; in 1884, they increased to 759 exchanges and 66 private lines; in 1885, to 1,129 exchanges and 72 private lines; in 1886, to 1,627 exchanges and 72 private lines; and in 1887, to 1,950 exchanges and 72 private lines. The calls were, in 1883, 838,690; 1884, 739,258; 1885, 1,089,626; 1886, 1,850,116; and in 1887, the average varied between 49,000 and 52,000 per week. The wire run amounted to 1,226 kilometres in 1883; 2,031 in 1884; 2,864 in 1885; 3,665 in 1886; and 4,217 in 1887.

During 1887 the new service of transmitting telegrams per telephone to and from subscribers was introduced, and although still new, has already been much appreciated; up to 1st December, 1887, in seven stations, 46,900 telegrams were transmitted by the Company. This result was obtained through the hearty co-operation of the Imperial Telegraph Officials with the Company.

This service is now beginning to pay its way, but its chief benefit is indirect, by bringing in many subscribers who otherwise would not have joined.

The charge per telegram is five kreutzers, or one penny. Compared with countries like England, France, Germany, and others, the Austrian provincial towns are few in number and have few inhabitants, and with a few exceptions are not commercial or manufacturing towns. They are situated at great distances from each other. The largest of the above is Prague, with 250,000 inhabitants, which is next to Vienna the largest town in Austria, whereas towns like Bielitz and Reichenberg have only 13,000 and 20,000 inhabitants. Considering these facts, it will be seen that the use of the telephone in Austria is quite up to the mark of any other country, and this is due to two causes: the first is the cheap price charged by the Company, varying as it does from £4. 15s. to £7 a year, and, secondly, to the great care taken to make their exchanges model exchanges both as regards line construction and apparatus.

All the lines are constructed of silicium bronze wire of 1·25mm. thickness. This wire can bear a strain of 80 to 86 kilos. per square millimetre before breaking, and has a conductivity of about 40 to 42 per cent. of pure copper.

Magneto calls are used throughout, and the apparatus are those known as the Gower-Bell and Consolidated.

The above statistics do not include those of the Vienna, Brunn and Linz Exchanges, which are worked by a different company. In Vienna there are about 1,200 subscribers, in Brunn about 250, in Linz about 180, total 1,630, which, with the total of Austria's subscribers 1,950, and private lines 72, brings up the number to 3,652. Apart from these there are a very large number of private lines in the country in those parts for which no concessions have been granted by the Government. These are almost all erected by the Government.

PORTABLE VOLTMETERS FOR MEASURING ALTERNATING POTENTIAL DIFFERENCES.

BY W. E. AYRTON AND JOHN PERRY.

(*Concluded from page 270*)

E.—Uniformity of the Scale Divisions.

It is rather important to notice that from (9) it follows that the smaller is $\frac{s}{r} y_0$ the more uniform become the divisions of the scale.

Now, from (15), $y_0 = \frac{t^3 l_0}{4 L b q} \phi_1$; so that $\frac{s}{r} y_0$ being small means, since $s = \frac{b}{a}$, that $\frac{1}{a r} \frac{t^3 l_0}{4 L q} \phi_1$ is small, or that $\frac{t^3 l_0 \phi_1}{4 L q a r}$ is small. But as a large maximum value of the deflection is very important, and as this, as we have seen, requires that t and r should be small, and that l_0 and q should be large, the only way in which we can simultaneously satisfy both sets of conditions is to make $n q$ large—that is, by using thick wires, many wires (as many wires as possible), and very thin strips for our magnifying spring. Using thick wires, however, diminishes the range of volts that can be measured.

Finally, it is to be observed that the condition of most importance in obtaining

(1) A large maximum deflection,
(2) Uniformity of the divisions of the scale,
(3) A large range of volts that can be measured,

is to make the strip of which the magnifying spring is made *as thin as possible.*

F.—Correction for Temperature.

In what precedes we have disregarded the effect produced by the variation of the temperature of the instrument as a whole, caused partly by variations of atmospheric temperature, and partly by the warming up of the whole instrument by a prolonged maintenance of the potential difference at its terminals. We will now investigate the magnitude of the error so caused.

Let a be the coefficient of expansion of the stretched wire;

β be the coefficient of expansion of the framework supporting the ends of the wire;

y_0 be the dip OQ (Fig. 10) at the temperature of graduation;

y_t „ „ $t°$ C. above „ „ „

y „ „ $\theta + t°$ C. „ „ „ „

then

$$y_0^2 + A Q^2 = \tfrac{1}{4} l_0^2,$$

$$y_t^2 + AQ^2 (1 + \beta t)^2 = \tfrac{1}{4} l_0^2 (1 + a t)^2,$$

$$y^2 + AQ^2 (1 + \beta t)^2 = \tfrac{1}{4} l_0 \{1 + a (\theta + t)\}^2;$$

$$\therefore \quad y^2 - y_0^2 = \tfrac{1}{2} l_0^2 a \theta + \tfrac{1}{2} t (l_0^2 a - 4 AQ^2 \beta).$$

If the initial dip at the temperature of graduation be small,

$$4 AQ^2 = l_0^2, \text{ approximately};$$

$$\therefore \quad y^2 - y_0^2 = \tfrac{1}{2} l_0^2 \{a (\theta + t) - \beta t\}.$$

Let

$$a - \beta = \gamma,$$

where γ can be made positive, nought, or negative by compensation of the framework of the instrument for changes of temperature. Hence

$$y^2 - y_0^2 = \tfrac{1}{2} l_0^2 (a \theta + \gamma t) \quad . \quad . \quad . \quad . \quad (17)$$

Also, if ρ_0 be the specific resistance of the material of which the wire is made at the temperature of the framework of the instrument during graduation, and if ρ be the specific resistance when the framework of the instrument is at a temperature $t°$ C. above that of the temperature of graduation, and when the wire has a temperature $\theta°$ C. above that of the framework,

$$\rho = \rho_0 \{1 + k (\theta + t)\}.$$

Consequently, following the reasoning previously given, connecting the rate of loss of heat by radiation and convection, and the rate of production of heat by the passage of the current, we have

$$\theta = \frac{V^2 d}{4 l_0^2 \epsilon \rho \{1 + k(\theta + t)\}}, \text{ approximately.}$$

Substituting in (17) the value for y given in (6), and for θ the value just obtained, we have

$$\phi^2 + 2 \frac{s}{r} y_0 \phi = \frac{s^2}{r^2} \tfrac{1}{2} l_0^2 \left(a \frac{V^2 d}{4 l_0^2 \epsilon \rho_0 \{1 + k (\theta + t)\}} + \gamma t \right)$$

$$= \frac{s^2 d a V^2}{r^2 8 \epsilon \rho \{1 + k (\theta + t)\}} \left(1 + \frac{\gamma t}{a \theta}\right)$$

$$= \frac{A V^2}{(1 + k \theta) \left(1 + \frac{k t}{1 + k \theta}\right)} \left(1 + \frac{\gamma t}{a \theta}\right),$$

or $\phi^2 + 2 \phi_0 \phi = \frac{A V^2}{1 + k\theta} \left(1 - \frac{k t}{1 + k \theta} + \frac{\gamma t}{a \theta}\right)$, approximately (18)

Now formula (8), obtained on the assumption that the framework of the voltmeter always remained at the temperature it was at during the graduation of the instrument, may be written

$$\phi^2 + 2 \phi_0 \phi = \frac{A V^2}{1 + k \theta};$$

hence the effect of the whole instrument being heated up to $t°$ C. is to diminish the right-hand side of the equation by the fraction $\frac{k t}{1 + k \theta}$ of itself, in consequence of the increase of the resistance of the stretched wire; and to increase the right-hand side of the equation by the fraction $\frac{\gamma t}{a \theta}$ of itself, in consequence of the difference of the coefficients of expansion of the stretched wire and the framework. If γ, the difference between the coefficients of expansion of the stretched wire and of the framework, be selected so that

$$\gamma = \frac{a k \theta}{1 + k \theta},$$

then for that particular value of θ there will be no temperature error of the instrument. Now the effect of γ not being nought will be to cause a slight motion of the pointer when the whole instrument is warmed up as a whole without any potential difference being maintained at its terminals; or, in other words, γ produces what may be called a zero error. Hence the zero error can be made such that there is no temperature error when the instrument is required to measure a certain definite potential difference or a potential difference of about that value. If, on the other hand, the framework of the instrument be so constructed that γ is nought—that is, so that there is no zero error—then the deflection corresponding with any given number of volts maintained at its terminals will be somewhat diminished as the instrument warms up as a whole. In order that accurate readings may be able to be made of small potential differences giving deflections near the zero it will be desirable to make γ small, but whether it ought to be made absolutely nought or not can only be determined by practical experience of this new form of voltmeter extending over some time.

Solving (18), we have

$$\phi = -\phi_0 + \sqrt{\phi_0^2 + \frac{A V^2}{1 + k\theta} \left(1 - \frac{k t}{1 + k\theta} + \frac{\gamma t}{a\theta}\right)} \quad . \quad . \quad (19)$$

and in order to estimate the magnitude of the error arising from the terms involving t let us consider the values of the constants in the previous expression. In some of our instruments we find that the initial sag y_0 is about 0·5 centimetre, and that $y - y_0$ is about 0·22 centimetre when ϕ is about 280° —that is, when the needle is deflected to the limit of the scale. Therefore, since

$$\phi_0 = \frac{s}{r} y,$$

and

$$\phi = \frac{s}{r} (y - y_0),$$

it follows that

$$\phi = \frac{\phi_0}{2}, \text{ approximately,}$$

Digitized by Google

when the deflection has about its maximum value. Hence, if we write X for $\frac{A V^2}{1+k\theta}$, X′ for $\frac{A V^2}{1+k\theta}\left(1 - \frac{k t}{1+k}\theta + \frac{\gamma t}{a\theta}\right)$, and ϕ' for the value of ϕ, when X becomes X′, we have

$$\phi = -2\phi + \sqrt{4\phi^2 + X}, \text{ approximately,}$$

and

$$\phi' = -2\phi' + \sqrt{4\phi'^2 + X'}, \quad \text{,,}$$

therefore the proportional error when the deflection is a maximum

$$\frac{\phi - \phi'}{\phi} = \frac{\sqrt{\frac{X}{5}} - \sqrt{\frac{X'}{5}}}{\sqrt{\frac{X}{5}}}, \quad \text{approximately,}$$

$$= 1 - \sqrt{1 - \frac{k t}{1+k\theta} + \frac{\gamma t}{a \theta}}, \quad \text{,,}$$

Now k equals 0 00031 and a about 0·0000145 for platinum-silver; also θ is about 250deg. C. when the deflection ϕ is about 280deg. Let t, the temperature through which the case of the instrument is raised above the temperature of graduation, be 50deg. C.; then, if γ be nought,

$$\frac{\phi - \phi'}{\phi} = 0{\cdot}007, \text{ approximately;}$$

that is, ϕ is diminished by about 0·7 per cent., in consequence of the increase of resistance of the stretched wire. And this temperature error can be made still less by giving γ a negative value—that is, by making the framework of the instrument have a larger coefficient of expansion than the stretched wire. For instance, if the framework which carries the stretched wire have a coefficient of expansion rather less than that of copper, the temperature error of the voltmeter in the higher parts of the scale will be practically nought.

The accuracy of the instrument depends, among other things, on the constancy of the elasticity of our magnifying springs. To test this we have had tests conducted regularly during the last two years on one of our magnifying spring ammeters. The current was measured absolutely on each occasion by the silver-deposit method, and, as this can be done more easily and accurately if the current be rather small, the ammeter selected for this series of tests was one that gave the maximum deflection (of about 270deg.) for 1½ ampere. Of course the only difference between this ammeter and a magnifying spring ammeter measuring a much larger current is in the gauge of wire used in the winding, and not at all in the spring; therefore any conclusions as to constancy that may be drawn from the results of the tests are equally applicable to any other magnifying spring ammeter. Sixty-four distinct tests have been made by different groups of students in the two years; and to impress on the students the importance of making such time tests of an ammeter, as well as to prevent their imagining that the silver-deposit test ought to give the same values for the currents as are indicated by the graduations of the scale of the ammeter, the students were warned that the ammeter had been intentionally graduated with an error—the error, in fact, being that the ammeter reads from 1½ to 2 per cent. too low.

Instead of giving the tests in the exact order in which they were taken, each group of tests is, for the convenience of comparison, arranged in chronological order.

As the tests were made by a large number of different students, having very different aptitudes for such work, some of the results arrived at were obviously wrong, and have been rejected; but, excluding these few exceptional ones, the preceding are a fair sample of the results obtained, and we see that it is impossible to conclude from them whether the ammeter has become more or less sensitive during the two years. In other words, its sensibility for practical purposes has remained quite constant. The temperature was carefully recorded after the early part of 1886, since it was thought that perhaps some temperature error might become visible; but this has not turned out to be the case, so that *the temperature may be apparently neglected in using a magnifying spring ammeter.* With a magnifying spring voltmeter wound with copper wire there will, of course, still remain the error due to a variation of the resistance of the coil with temperature; but the important result that has been arrived at is that *the indications of a magnifying spring ammeter or voltmeter, when a given current is passing through it, is not altered by age or by the ordinary changes of temperature of a room.*

Tests made with a Magnifying Spring Ammeter initially graduated from 1½ to 2 per cent. too low.

To further test this latter point a magnifying spring ammeter, adjusted so that the needle stood exactly at zero when the temperature was about 15° C., was placed in a bath and heated up to 40° C. for five hours; but no marked change in the zero could be observed, which would have been the case if the elasticity of the spring had sensibly varied, seeing that the weight of the soft iron cylinder was hanging at the end of the spring all the time. We feel, therefore, quite safe in using the magnifying springs for our new type of voltmeter.

We are now engaged in devising various means for compensating this new form of voltmeter for temperature errors; but before actually introducing these compensations into the instruments one of our students—Mr. Kilgour—has been carefully measuring the exact coefficient of expansion with temperature of fine platinum silver wire under a tension which is comparable with its breaking tension. The compensation for the short-tube form shown in Figs. 3 and 4 will probably in part consist in the device adopted by Captain Cardew of making the support to which the wires are attached of a compound metal; while in the case of our bicycle-wheel form the rim to which the wires are attached will probably be made like the balance wheel of a chronometer; but of course the same accuracy of adjustment for temperature that is necessary in a

Digitized by Google

chronometer will be quite unnecessary in the voltmeter, as the error is not a cumulative one as it is in a chronometer.

The following, we venture to think, are the improvements that we have been led to introduce into the Cardew voltmeter by employing the devices that we have described :—

1. A small alternating potential difference can be accurately measured, as the wire in our instrument may be short, and as the readings can be taken down to zero with certainty.

2. With the same instrument a wide range of volts can be measured, since with many short wires combined with a commutator any number of them can be put in series; that is, any length of wire can be electrically used.

3. Whatever number of volts is being measured, all the wire is directly active in deflecting the pointer, which is not the case with an instument provided with an external resistance for increasing the range.

4. The instrument is compact and portable.

5. Great dead-beatness of action is secured by the employment of much finer wire than has hitherto been commercially used, and by the magnifying gearing being frictionless and comparatively massless.

6. Non-liability of even such fine wire to break from a blow, in consequence of the frictionless and comparatively massless character of the magnifying gearing to which the wire is attached.

7. Diminution in the power wasted on the instrument by the employment of a short instead of a long wire.

SAFETY FUSES FOR ELECTRIC LIGHT CIRCUITS.

BY MR. A. C. COCKBURN.

The following is an abstract of the paper by Mr. A. C. Cockburn, read before the Society of Telegraph-Engineers and Electricians on the 8th December, "On Safety Fuses for Electric Light Circuits, and on the Fusing Points of Various Metals usually Employed in their Construction." The author points out that inefficient fuses, which are often used for the sake of cheapness, are in themselves a source of danger, and gave instances of fires the origin of which had been traced to defective fuses. He insisted on the importance of using double pole fuses, viz., placing a fuse upon each of the leads. According to the author, the following are the principal conditions which should be fulfilled by a good fuse :—It should act with certainty within 5 to 10 per cent. of the current strength at which it is intended to fuse. It should not alter much with time. The contacts should be such as to allow, without dangerous heating, the passage of at least three times the maximum current which they are intended to carry. The material should not be readily oxidisable ; the wire or foil should not touch the case. The case or fuse holder should only admit the fuse specially intended for it, and should be such as can easily be fitted up by an ordinary workman. The leads should not cross. The fuse should be easily replaceable when broken. The holder should be of non-inflammable material. It should be so inexpensive that reasons of economy may not prevent its use, even for single lamps ; and, finally, the fuse should, whenever possible, be in sight, and covered only by a transparent substance, such as glass or mica. Moving parts are in general to be avoided, owing to their liability to stick ; but there is no objection to the use of electro-magnetic cut-outs on main circuits, provided they are well constructed, and proper attention is given to keep them in working order.

According to the author's experience, foil cannot be depended upon within sufficiently narrow limits of current strength, and it has the additional disadvantage of requiring to be supported throughout its length.

Prof. S. P. Thompson's fuse, in which the leads are joined by means of a button of fusible alloy, was described, and also one devised by Sir W. Thomson, in which the fuse leads consist of springs, joined by a button of fusible alloy, and which fly apart when the alloy melts. If plain wire could be depended on, it would be preferable, as the fuses could be made more cheaply. For this purpose iron is objectionable, because it oxidises readily if exposed to damp, and owing to its high fusing point it would be dangerous if used in a wooden holder which had not been made thoroughly fireproof. Copper and platinum are both open to the same objection of too high a fusing point, and copper is also found to change its fusing point after repeated heating. Lead is difficult to draw, and is very liable to damage on account of its softness, and in common with copper and iron, it oxidises very readily when heated by the current.

The metal which the author finds best is tin containing about 5 per cent. of phosphorus. It does not oxidise very readily when heated, and not at all from moisture, and it melts at 235deg. C., a temperature at which wood is not charred. Slow oxidation does take place when it is heated, and this has hitherto been the principal difficulty in the way of using simple wire fuses, as the film of oxide formed on the outer surface of the wire may retain the molten metal within it and prevent the circuit from being broken ; and though it has been attempted to remedy this by placing the wire in a vertical position, the attempt has only been partially successful. The author has got over the difficulty in a very simple manner by placing a small leaden weight on the wire, which breaks the film of oxide, as soon as the metal assumes the pasty condition through which it passes before becoming molten, and he finds that in this manner a definite fusing point, well within 10 per cent. of the current strength for which the fuse is intended to act, can be attained. An experiment was shown in which the same current was sent through two perfectly similar wires, except that one was weighted and the other not. As the current was very gradually increased, the unweighted wire attained a dull red heat, at which point the weighted wire broke without having reached redness. This experiment is very curious, as it shows that the effect of the weight is not merely to break the wire, but that with the same current the weighted wire does not attain so high a temperature as the unweighted one. It is true that the leaden weight, owing to its heat conductivity, would abstract a small quantity of heat from the centre of the wire, and owing to its electrical conductivity would slightly diminish the resistance of the small central portion of the wire in contact with it, and therefore slightly diminish the development of heat in that part ; but though these minute actions might possibly produce an appreciable effect in the part of the wire immediately adjacent to the weight, it is difficult to imagine that they could do so in the more remote portions. The fuses are made in standard lengths, and are all tested up to near their fusing point before being sent out, to ensure their not fusing for too low a current strength.

LEGAL INTELLIGENCE.

Anglo-American Telegraph Company (Limited) versus La Compagnie Francaise du Telegraphe de Paris a New York.

The following is the text of the judgment which was delivered by the Tribunal of Commerce of the Seine in this case on the 9th January, 1888 :—

The Tribunal decides :—

Whereas, to justify the rupture of the agreements which bound them to the Anglo-American Telegraph Company (Limited), the French Telegraph Company from Paris to New York puts forward a Ministerial despatch which had been addressed to them in Paris under date of the 30th December, 1886, that they allege that the existence of the relationship complained of had been subordinated to the authorisation of the French Government, and that the Minister objecting to-day to this relationship as would appear to result from the letter before-mentioned, the French Company, in repudiating the agreements, was supposed to remain under the conditions of the contract, and could not under these conditions be held responsible for any damages any more than for a resumption of this relationship ;

But seeing that it is shown by the pleadings and the documents submitted to the Tribunal that by verbal agreements entered into in May, 1882, the two companies parties to the suit had established between themselves a *modus vivendi* in the working of their cables between Europe and the United States for a period of 46 years, which should be reduced to 22 years, at the option of the parties ;

Whereas this agreement, which had for principal object to suppress the competition between the two companies, formally stipulated that the said agreement should leave intact, independent and distinct, the capital of each company, its concessions and authorisations ; that the results, good or evil, of their respective enterprises, should remain for the account of each of them, and that there should not be between them any fusion of interest, each company keeping its particular administration, its *employés*, and its special agents ;

Whereas, moreover, Article 9 of the Specification of the Concession made to the French Company recites that the Concessionary shall not make over his rights, lease his lines, nor make fusion of his interests without the consent of the French Government ;

Whereas that, although the contracting companies had come to an understanding not to make any fusion whatsoever of their interests, they stipulated, nevertheless, that their understanding should not take effect except after the Governmental authorisation,

Digitized by Google

which might be necessary for the French Company, had been solicited and obtained, if need should arise, and that in default of ratification or of authorisation within the period fixed at sixty-five days, then prorogued to 113 days, these agreements should be considered as null and of none effect;

Whereas it is acknowledged at the Bar, and not denied by the French Company, that the latter asked for the Governmental authorisation;

Whereas it is established and recognised equally at the Bar by both parties in evidence that, in reply to this demand it was declared by the Minister that the agreement which was submitted to him, not coming within the prohibitions of Article 9 of the Specification, there was no need of any authorisation;

Whereas, the board of directors of the French Company in the report presented to the shareholders of the company at the ordinary general meeting on the 11th May, 1881, declared, on the subject of the said authorisation:

"We have assured ourselves that the Governmental authorisations are not necessary to us" . . .

Whereas, then, from that time, nothing being opposed to the execution of the agreements, the latter received their application, and that these agreements, perfectly known to the French Government, were executed more than five years without there having been raised any objection;

Whereas that, if on the 30th December, 1886, the competent Minister interpreting the agreements otherwise than his predecessor thought fit to recall the French Company to the integral carrying out of the clauses of its specification, this new and unexpected interpretation of the parties to the suit could not create, as is alleged by the French Company, a case of *vis major*, putting them under the obligation of breaking immediately their engagements;

That, in effect, Article 14 of the Specification recites:—"That if differences should be raised between the French Government on the one part and the Concessionary or the Company on the other part on the subject of the interpretation or of the carrying out of the concession, these differences shall be adjudged administratively by the Council of Prefecture of the Seine, subject to appeal to the Council of State;"

That it therefore was incumbent on the French Company to appeal to the first interpretation given by the French Government in bringing to the knowledge of the Minister in power the assurance which had been given by his predecessor, that the Convention of the 12th May, 1882, did not come within the prohibition of Article 9 of the Specification, and that there was no need of any authorisation;

That it appears to be established that the Minister was not made acquainted with this decision of his predecessor;

Whereas, for the rest, the Ministerial despatch of the 30th December, 1886, could not constitute a legal notice calling for an immediate cessation of all relationship between the co-contracting companies;

That it was incumbent at this moment on the French Company to have recourse to competent jurisdiction, to obtain the maintenance of agreements confided to them in good faith;

That in not doing this, and in interpreting as they did the Ministerial despatch of the 30th December, 1886, they permit of the supposition that they had an interest in that the verbal agreement of May, 1882, should not be executed;

That this method of acting constitutes a violation of the agreements entered into which involves their responsibility;

That there is reason under these conditions to recall them to the respect of engagements subscribed to by them, and to compel them to resume the execution of them within a certain delay and under a constraint which will be mentioned presently, and to pay to the plaintiff company by way of damages a sum which the Tribunal fixes at £80 per diem, from the 31st December, 1886, until the day of the resumption of the working, if it takes place before the signification of this present judgment; if not, then up to the date of the said signification.

For these reasons:—

The Tribunal decides "that on the day of the signification of the present judgment, the French Company, Paris to New York, must resume the execution of the agreements of the 24th September, 1880, and the 12th May, 1882, and that, until it has been absolutely adjudged by competent jurisdiction as to the value (force) of the Ministerial declaration of the 30th December, 1886, the whole at a penalty of £200 per diem of delay, during one month, after which justice will be done (upon a further application);

"Condemns the French Telegraph Company, Paris to New York, to pay to the Anglo-American Telegraph Company (Limited), by way of damages, a sum equivalent to as many £80 as there may have elapsed days from the 31st December, 1886, up to the resumption of the agreements if this has taken place before the signification of the present judgment, and if not, then up to the day of the said significatino;

"Condemns the French Telegraph Company, Paris to New York, in costs."

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *Jan.* 14*th*, 1888.

I mentioned in my last letter the fact that the next meeting of the National Electric Light Association will be held at Pittsburgh. I may add now that there is a probability that the president, Mr. J. F. Morrison, will carry out his long-delayed intention of resigning that office. The association has been built up largely through Mr. Morrison's efforts, and he has given no little time and attention to its affairs. More than once before he has sought to relinquish the office, but each time he has been so earnestly requested to continue that he could do nothing else but hold on. His business engagements of late, however, have grown so numerous and pressing that he feels he must insist on carrying out his wishes in this respect. This resolve on his part is universally regretted. It is understood that Mr. Morrison's successor will probably be Mr. S. A. Duncan, of Pittsburgh. Mr. Duncan is one of the young men who have come to the front in electrical enterprises in this country by their industry and ability, and he is to-day identified very prominently with lighting and motor interests in the city above named. It is interesting and suggestive that, like Mr. Morrison, he is an old telegrapher, and was induced to leave the more familiar field by the promises held out in the new, which has been so fruitful of good results for men of the right stamp. The importance of the position in the eyes of the public may be inferred when I state that recent estimates show the existence in this country of 1,000 central stations and 3,000 isolated plants, arc or incandescent, or both.

These plants have a capacity in the neighbourhood of 200,000 arc lights, and a million and a-quarter incandescents, and operate a great many motors as well. Where an industry is susceptible of so many changes and developments, it is very difficult to get at the closest figures with regard to it, but the statistics just given are a safe approximation to the actuality.

As a matter of personal gossip, in this connection it may not be out of place to say that Mr. Morrison is not simply a successful executive officer or a mere business man of push and enterprise. At his home in Baltimore are to be found excellent specimens of the work of our best American painters; some of them purchased when those artists did not enjoy the vogue they now have; but the most interesting thing there to electricians is his fine electrical library, which is rich in old and rare editions, and includes every one of the electrical books issued in recent times. It is also noticeable as containing complete files of technical journals and publications, which are extremely difficult now to duplicate. On this library Mr. Morrison has spent many thousand dollars, and it is steadily growing. There are not very many such private collections in this country of electrical literature. Prof. Alexander Graham Bell probably possesses by far the largest and the best. Mr. Edison has a magnificent library of scientific books, which for some months past has been slowly getting into order at Orange. Mr. Edward Weston has also a remarkably fine and choice collection, including such famous first books as Gilbert and Volta. Perhaps the choicest, though not the largest, collection of rare electrical books in America is that of Dr. Park Benjamin, the well-known expert, and the author of the popoular "Age of Electricity," and numerous magazine articles, &c. It is said that this collection embraces works that were not included even in the well-known Latimer Clark library. It is certainly one of great value, the possession of which every bibliophile must greatly envy Dr. Benjamin, who, it is to be hoped, will some day put forth the results of his long and patient researches in this field. Early electrical literature is to-day little read or understood, and a master hand is required to sweep away the blunders, and misstatements, and misconceptions that have buried the work of the old worthies, or upon which have been built up unstable reputations.

A small sensation was caused here this week by the announcement in some of the daily papers of New England that tele-

Digitized by Google

phone counsel had been summoned to Washington by the Supreme Court. This, of course, was interpreted to mean that the Supreme Court intended to hand down its anxiously-awaited decision in the telephone cases. The fact was, however, that no such summons had been sent out, and that no decision was given out; and so we must possess our souls in patience a little longer. An important opinion with regard to telephones has, nevertheless, been given recently by a Western Court, which held that under the law of the State the telephone company was bound to furnish every applicant with a telephone and proper connections at the statutory rate. The company objected on the ground that it was doing merely a toll line business, into which such legislation had, in fact, forced it; but the Court did not admit the validity of this plea. In New York some consolation is derived from the understanding that the Legislative Telephonic Investigating Committee will present a comparatively mild report. It was stated before the committee that you had better telephone service in London than we have here. We are hardly inclined to believe this, and it is not thought that the committee will take such a view of the case, nor that it will report very severely as regards the rates charged.

Some idea of the extent to which electric lighting is being pushed in this country may be formed from the fact that the new premises in which the Consolidated Electric Light Company will carry on the manufacture of the Sawyer-Man lamp in this city covers thirteen city lots. It is a six-story building with a frontage of 325ft., and has a floor space of 117,000 square feet ready for use. This is, it would seem, the largest incandescent factory in the world, and it certainly will be without rival if it manufactures, as is claimed to be the intention, from five to ten thousand lamps per day. When it is borne in mind that other lamp producers are manufacturing on a more extensive scale than ever, it will be seen that the promoters of electric light enterprises face the future with equanimity. This, in spite of the fact that innumerable new systems of making and burning gas are being sprung upon the public. We have had all sorts of crazes of this kind here, including the Welsbach, which seems to have run its course, though while it was at its height scores of companies with millions of capital were organised in all parts of the Union. There is no doubt, however, that improvements will be made here in the direction of the greater use of fuel gas, and it may be noted that Mr. C. M. Lungren, C.E., is introducing a system of the Welsbach character, but superior in many respects, and using an incandescent spiral of unusual cheapness and longevity. Mr. Lungren claims great economy for his system over electric lighting and other forms of illumination, and as a number of shrewd men prominently identified with telephone interests have given him a certain amount of support, it would seem that he has something really meritorious; but it is not at all apprehended that electric lighting interests will suffer from the introduction of this or any other method of utilising fuel gas for light at the place of consumption. On the contrary, the belief is growing that we shall see no small development in the way of utilising fuel gas to drive gas engines, in their turn operating dynamos for electric light and power.

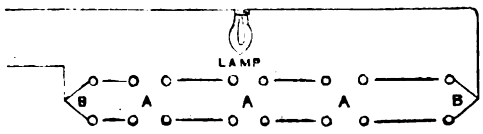
Already an extensive use is being found for the storage battery in central station plant. This has been especially the case in Pennsylvania, where plants of this kind are now to be found at Allentown, Bethlehem, York, and Reading, and where new installations are contracted for in Philadelphia and Harrisburg. It is not altogether to be expected, however, that work of this kind would be attempted in the furthest removes of the Far West; but it is worthy of note that a plant has just been put in at Burrtown, one of the newest towns in Kansas. As one of the local journals says:—"Burrtown, although one of the smallest cities in the world, is by no means behind others of larger proportions in the great race for progress. This assertion can be readily bolstered up by numberless arguments, the chief one of which is the fact that an electric light system, the equal of which can be found in several Eastern cities, but its superior in none, has been established and put in operation within the past few weeks. At the present time Burrtown is being talked of more perhaps than any city in the country." I am glad to lend my help in securing for Burrtown this proud distinction and wide-spread publicity, and, after all, the embryo Kansas settlement deserves commendation for its enterprise. The plant in question uses the well-known batteries of the E.P.S. type, made here by the Electrical Accumulator Company. In Kansas City, also, considerable use is being made of storage batteries for lighting, and it is not at all unlikely that several other plants in the State will soon follow this example.

CORRESPONDENCE.

INDEPENDENT SWITCHES FOR ONE LAMP.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should like to point out to you that the method of controlling a lamp or group of lamps from either one of two points, which you described in your last issue, may be increased to control them from any number of independent points in the following manner:—



The switches at B B are plain two-way switches, but the intermediate switches at A are reversing switches. It will be seen that reversing any one of the switches will light the lamp if it be extinguished, or extinguish it if it be lighted. If some of our electric light fitting makers would give a little attention to cheap and compact two-way and reversing switches such a plan as this might be adopted with advantage in many places where people would hesitate long before using an electromagnetic switch.—Yours, &c., R. H. C. NEVILE.

Wellingore Hall, Grantham, Jan. 23, 1888.

PRESERVATION OF OVERHEAD WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I invite Mr. Bozon to state in your columns the weight of his india rubber compensator, which, as he says, yields ¼in. per ½cwt. stress. My steel springs, if yielding only ¼in. per ½cwt., would weigh barely 1½ *ounce* per span. Such a slow rate of yield would be practically useless.

A copper wire of 100 yards span needs a relief not of ¼in. but of nearly 4in. per ½cwt. stress per span to save it from storm stresses. My double steel springs, therefore, weigh nearly 1½lb. I think Mr. Bozon will find it necessary to *multiply by 16* the weight of his india rubber. And this at 4s. per lb. must make it much too costly, as well as too heavy, to say nothing of its liability to decay.

I cannot see that Mr. Bozon's arrangement prevents (as mine does) the destruction of the line wire by chafing at its attachments; nor can I see that Mr. Bozon would improve insulation, &c., by cutting the wire at each post, and passing the current through the compensator itself; while my spring shackle preserves continuity of line wire and greatly improves insulation.

Further, it does not seem to have been Mr. Bozon's object to utilise the form of insulator in most approved use. I have utilised it, though my spring shackle is suited to other forms of insulator also.

Although I regard Mr. Bozon's application of india rubber as utterly impracticable, I may add that he cannot use it as he proposes without infringing my patent rights.

I take this opportunity of inviting public attention to the fact that no writer has yet succeeded in sustaining one objec-

tion to my spring shackles. It cannot be denied that they would greatly prolong the life of the wires, while improving the insulation and preventing interruption. And if spring shackles are employed, silicon bronze wire for long spans need not be substituted for copper wire. Moreover, for over-house and over-street long spans spring shackles would obviate the necessity for such an extension of Parliamentary powers as is now meditated by telephone companies.—Yours, &c.,

Sunderland, January 21, 1888. FRANK CAWS.

"HANDBUCH DER ELEKTRICITAT UND DES MAGNETISMUS."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have noticed that in your review of the lately published "Handbook of Electricity and Magnetism," by Dr. O. Frölich, on p. 12 of the current volume of *The Electrician*, you specify the same as the 2nd edition of the 2nd Vol. of my "Handbook of Telegraphy."

An authority for this statement may have been found in the text of the preface to the first-mentioned work.

Will you allow me, therefore, to draw your attention to the fact that this new book does not form a part of my "Handbook of Electric Telegraphy," and as you may now see by the revised preface, which I enclose, wherein the passage in question, on my request, has been put into a different form for the sake of preventing any misunderstanding.—Yours, &c.,

Dresden, Dec. 19, 1887. E. ZETZSCHE.

[Dr. O. Frölich, referring to this matter in the new preface (a copy of which Dr. Zetzsche encloses in his letter), says:—

"The above preface appeared in the second volume of Prof. Zetzsche's 'Handbook of Telegraphy,' written by me in 1878.

"This present 'Handbook of Electricity and Magnetism' is only connected with the first-mentioned work so far as the points of view, the arrangement of the material, and the manner of treatment are concerned. But the book is intended for a larger circle of readers, and contains, therefore, essentially different and additional matter, especially with regard to the technical portion of the subject."]

ELECTRICITY AND DOCTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your Notes of to-day you venture to criticise a paper by Dr. C. B. Radcliffe "On the Electrical Basis of Vital Motion," in which he does not appear satisfied with the electricity generated in the organic system, but must seek "an electrical action extending to the whole solar system and not limited to it."

If you will turn to *The Electrician*, Vol. IV., you will find a review of Dr. Radcliffe's course of lectures on "certain disorders of the brain," &c., in which he then appeared satisfied with the electricity found in the system as accounting for all muscular energy, &c. That Dr. Radcliffe was searching in the right direction was confirmed by Continental electro-physiologists and by the interesting experiments of Dr. Shettle. He must now, however, throw up a cloud of nebulous matter collected from space to account for the electrical basis of vital motion, to conceal his inability to explain it. As your journal has become the organ of the electrical engineer and not the electrician, I will not ask *your* readers to wade through Vols. IV. and V.; but should any electro-physiologist care to study the subject he will find ample information contained therein to elucidate this question. In brief, my lectures were written to demonstrate chiefly the generation of nerve force in the capillaries, the result of the electric tension existing (proved) between the arterial and venous blood.—Yours, &c., HARRY LOBB.

66, Russell-square, January 20th, 1888.

[We have received, too late for insertion in this issue, a letter from Mr. J. M. V. Money-Kent on the same subject.—ED. *E.*]

THE TELEGRAPHISTS' SCHOOL OF SCIENCE, ST. MARTIN'S-LE-GRAND.

The eleventh annual prize distribution of this school took place on Friday, the 13th inst., in the Postmaster-General's Deputation Room, Mr. H. C. Fischer (Controller of the Central Telegraph Office) in the chair, supported by Mr. C. H. B. Patey, C.B. (Secretary to the General Post Office), Mr. W. H. Preece, F.R.S. (Electrician), and several chief officers of the department, including Messrs. Lamb, Ardron, Macgregor, Ogilvie, Hookey, May, Barlow, and J. T. Hill.

In the report, read by the SECRETARY of the School, it was shown that great success had attended the teaching of Mr. Slingo and his assistants Messrs. Miles and Brooker. Nineteen out of 25 candidates in magnetism and electricity, and 5 out of 6 candidates in mathematics, were successful; 15 sat for examination in telegraphy under the City and Guilds of London Institute: 2 failed and 13 were successful, 10 of them taking first class certificates. Mr. F. Tandy, a promising young student, gained the first prize in the United Kingdom, viz., a silver medal and £5, with a first class honours certificate. He also took first class certificates in electricity and mathematics. Thirty-five local prizes of considerable value were also awarded, the three principal being aggregate prizes for general success. The first, value £2, was awarded to Mr. F. Tandy; the second, £1. 1s., to Mr. J. Bailey, and the third to Mr. W. J. Callow. The report drew attention to the fact that in telegraphy 13 out of 73 certificates in the United Kingdom were gained by members of the school; also, that as twenty-four schools were represented, the average success was only three certificates per school, as against the above-mentioned thirteen. During the twelve years that the school has been in existence, 353 members of the staff have passed through the classes, and have gained considerably over 400 certificates. During the past four years five medals out of twenty-six awarded for telegraphy in the kingdom have been gained by the school.

Mr. PREECE, in distributing the prizes, congratulated the school on its success, and on having Mr. Slingo for its teacher, and impressed upon his hearers the great advantage of technical education and the necessity and advisability of continuing the studies so well commenced. He laid particular stress upon the need for continued study and application at home, and believed that the real duty of a teacher was to direct the studies and regulate the thinking power of his pupils. It was the student's duty to inquire fully into every detail, and never to believe an experiment until he had performed it himself.

In responding to a vote of thanks Mr. PREECE said he hoped an opportunity would soon offer itself for increasing the work and efficiency of the school, and Mr. PATEY, in responding for the department, said no effort would be spared to ensure the continued success of the classes, and hoped that the time would soon come when the work would be so heavy that it would be necessary for Mr. Slingo to devote his whole time to the interests of the school.

A hearty vote of thanks was accorded to the Chairman, who said in response that he had noticed with pleasure the gradual and sturdy growth of the school, and promised that every facility should be afforded to members of the staff joining the classes.

BOOKS RECEIVED.

"Practical Physics for Schools;" Vol. I., "Electricity and Magnetism." By Prof. BALFOUR STEWART and Mr. HALDANE GEE. (London: Macmillan and Co.)

"Papers of Fleeming Jenkin, with a memoir by Mr. R. L. Stevenson." 2 vols. (London: Longmans and Co.)

16,661, 1886.—R. P. SELLON and OTHERS.—Self-regulating dynamo-electric generators. (Price 8d.)
266, 1887.—E. EDWARDS. Electric telegraphs. (Price 1s. 8d.)

COMPANIES' MEETINGS.

The Eastern Telegraph Company (Limited).

The thirty-first half-yearly ordinary general meeting of the Eastern Telegraph Company (Limited) was held on Thursday, January 19th, at Winchester House, Old Broad-street, London, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY read the notice convening the meeting, and the minutes of the thirtieth half-yearly ordinary general meeting of the shareholders, held on the 14th of July, 1887, which were signed by the Chairman; and the report having been at the request of the meeting taken as read,

The CHAIRMAN said: I will now, as usual, make a few remarks so as to supplement the report, and give you such information as we think it desirable that you should have. The revenue for the half year ended September, 1887, amounted to £291,265, as against £292,229 in the corresponding half year of 1886, being a decrease of £964. The Directors, however, consider that this is satisfactory, because the decrease of revenue caused by the reduction of tariff to India has sensibly diminished, and indeed the improved traffic with Australia, China, and other countries in the far East has more than recouped the loss in Indian messages. Our traffic with Egypt, on the other hand, shows another falling off; but this has been made good by an increase of messages exchanged with Portugal and South America. Having so many points for the interchange of traffic, we find sometimes that the loss made in one direction is at other times made up by the increase in other directions. For the current half year our prospects are favourable. Our traffic now shows a small increase every month, and it is hoped that next July, when we present the accounts for our financial year to the 31st of March, we shall be able to give the shareholders a bonus in addition to the 5 per cent. dividend. The total working expenses amounted to £79,936, against £81,021, or a decrease of £1,085. With the exception of the expenses of redemption of 5 per cent. debentures and the issue of 4 per cent. stock, £912, we have had no expenses of an exceptional nature, such as, for instance, are inevitable in time of war. The general expenses in London were £8,012, against £7,964 in 1886. Some of the items under this head are more and some less, the net difference being a small increase of £48. The expenses at stations were £56,386, against £58,129, or a decrease of £1,743. The principal reduction, however, is in repairs and renewals of cables, which this half year amounted to £34,102, against, in the same period of 1886, £53,965, or a decrease of £19,863 upon the half year. Therefore, after charging all the expenses, including income-tax, providing for interest on debentures, debenture stock, and preference shares, we are able to pay an interim dividend on the ordinary shares at the rate of 5 per cent. per annum, and to carry forward to next half year a balance of £29,397, or £16,306 more than at the same period of 1886. Gentlemen, before asking you to approve of the report, I shall supplement the statement which I have just put before you by a few words of explanation and encouragement. In the speech I made six months ago I referred very fully to the position of the Company, not only at the moment, but as to its prospects, and as to the work it had before it. I referred then to the loss of income that was forced on us at the Berlin Conference. That loss caused for a time the suspension of our bonus, because it practically took away the amount we required to pay the bonus. However, last half year, if you remember, we announced at the close of the half year a bonus of ½ per cent. I also told you then that the bonus, we had decided, should, as a rule, be dealt with once a year. I have shown you to-day that we are carrying forward a very considerable sum, but until we close the year there is always an amount of uncertainty that what may be a large sum to carry forward to-day apparently may be materially reduced by serious interruptions to our

Digitized by Google

cables. I may tell you that our ships are constantly employed in making repairs, and though our costs for that during last half year were £19,000 less than in the corresponding period of the previous year, still our ships are constantly employed; but, as I have said before, while we can repair, it proves the value and solidity of our property. I am hopeful that, as we improve more or less the quality of our cable which we put into the sea, we shall lessen those repairs. If we could be free from those repairs I need not tell you that we should be able to pay you very handsome dividends. I referred also to our having just completed our Tangiers cable. That cable was laid by us, and was supposed to have been laid, by some of the Powers probably, without consulting sufficiently the Sultan of Morocco. However, the cable was a necessity. We accepted the position of laying the cable, and it is working now, and not only benefiting the Sultan's dominions, but also materially helping the Company. We have therefore done a good work, and probably, having shown a little energy in carrying it through, we have done so to the satisfaction of all parties, and there is no chance now of the Tangiers cable being disturbed. I also referred to the difficulties we had at that time with the French Government with respect to the renewal of our wire through France. That has always been useful as a stand-by, but for reasons which I cannot well explain (and it is difficult to do so, because we put a good deal of money into the French exchequer for that wire) we cannot yet get a renewal of it, and that line, the concession for which expires next year, we have not yet been able to get renewed. We have, however, as I have told you before, decided to make ourselves thoroughly independent, and we have laid a fresh cable from Porthcurno to Lisbon, Gibraltar, Malta, and Zante. I stated at the last meeting that when this cable was laid we should be able to give a good account of it by showing how we were going to recoup ourselves by savings in other quarters. The new cable has done its work in the most satisfactory way, aiding us in carrying our traffic more satisfactorily, and placing us in a perfectly independent position if war should break out on the Continent to-morrow. In these days of scares I think it is the duty, and it has always been our policy, to be ahead of the requirements both of the Government and of the telegraphing public. Thanks to the policy of the Company in duplicating our system, our system is now almost entirely duplicated, and triplicated as far as Aden. Had we depended on one wire, with the interruptions that constantly take place, and the employment of our steamers from day to day in effecting repairs, it would have been most unsatisfactory in every sense. It would have interfered with your dividends, it would have interfered with the telegraphing public, and it would have thrown discredit on the whole telegraphing system. We have entirely got the better of that by duplicating, and in some cases by triplicating our system. There are breakages now that the public know nothing about. We carry the traffic just as well as if every yard of our cable were in good condition. But you see in the accounts considerable expense connected with the repairs which we have had to make. Still, they do not interfere with the telegraphing public, or with you and your dividend. Therefore, I think you will admit that the policy of the Company in securing a continuous system is the only policy which can ever make submarine telegraphy prosperous and great. It has become great, and your Directors are determined, in future as in the past, to maintain that continuity, so as never to allow it to be said at any time that our system is not operative.

I referred at the last meeting to the improvement generally in trade, and I said that the telegraph was a great barometer of trade. I am glad to say that trade is still improving with our Colonies, as is evidenced by our having recouped the amount of money which we were obliged to give up in the reduction of tariffs at the Berlin Conference. That state of things brings us into the position, as I have said, at the end of the year, not only to pay you a dividend, but I hope a bonus, probably of 1 per cent. If we get back to the old 1 per cent. it would be satisfactory for a time, but we shall be able to show you distinctly from the figures whether we can pay you more or less. If we can give you more we shall always do what we conceive would be appreciated by our shareholders. You may say, "Why do you not pay us a bonus to-day?" (hear, hear). Well, that is quite a proper view, but we have to look a little ahead. There is a great deal of excitement in trade, more or less, particularly in Africa, where we hear about gold and diamonds, and if we were to believe all that we read about of these things we should have such a traffic, and there would be such an extension of trade, that it would place us in a very satisfactory position indeed. We are not quite disposed to be led away by these very sanguine views. We believe that gold is to be found in quantities in South Africa, and we know what gold discoveries have done for California. I hope they will do the same for South Africa if it is found in the same quantities there. The trade of this country very much needs it, South Africa wants it, and this Company needs it also very much in increased dividends. Six months hence we shall know something more as to whether this "boom" has sprung up on a strong foundation. If so we shall be able to pay you a dividend and a bonus corresponding.

There is another question that will, I think, be very satisfactory to you, as showing you the position this Company holds in the estimation of the commercial mind of London. We have replaced £450,000 of our Five per Cent. Debentures with Four per Cent. Debenture Stock. We first issued our Four per Cent. Debenture Stock at £95. When we made the exchange the other day we were able to get a small premium on the par value, showing that a Four per Cent. Debenture Stock of ours is considered a sound investment in the City of London. One gentleman I met lately, an eminent accountant and a Member of Parliament, said that nothing had struck him more in connection with the submarine telegraph system than the successful issue of our Four per Cent. Debenture Stock. I hope that that credit will continue. At all events, the policy of the Board will be to maintain the credit and efficiency of the Company.

There is another point that I think it well to give you some little information upon—that is, our reserve fund. I want to show you how we have kept down our capital, how we have applied the reserve fund in a good many instances to giving security to our dividends. If we had kept our reserve fund intact, and laid our new cables out of capital, we should have added close upon half a million to our capital. Instead of that we have drawn from the reserve fund from time to time, and at the same time taken from our annual income, and have thus built up all this duplicate and triplicate system from our income and reserve funds. If all the money we had put to the reserve fund had remained in the reserve fund to-day, that fund, instead of being what it is, would have amounted to over one million sterling. Now I think you will approve of that policy. It is a bad thing to overburden any system with capital, and as long as we can pay a satisfactory dividend, and secure that dividend by additional cables, I think it is the best policy for us, and it is the best for the shareholders also. It might please the shareholders to have an extra one or two per cent. to-day, but our policy is to place this Company in such a position that people will look with some certainty to their 5 per cent., and, when good times come, to a bonus corresponding to the success of the Company. I think I might mention the large sums that we have taken out of our reserve fund. We took to duplicate the Red Sea and Indian Ocean cables £100,000; we took to triplicate the Red Sea and other cables £300,000, we took for the Sicily and other cables, &c., £34,803. Altogether, therefore; we have taken out of the reserve fund something like half a million to consolidate and strengthen our position. With these remarks I think I have pretty well finished the information that I desire to give you. I think I may fairly end my observations by congratulating you on the prosperous condition of the Company at the present moment—prosperous because it is built on a sound foundation—and, I think, from that foundation we shall from time to time be able to show you that the superstructure is sound. With these remarks I beg to move:—

"*That the report and accounts of the Directors to the 30th of September, 1887, submitted to this meeting, be and the same are hereby received and adopted.*"

The VICE-CHAIRMAN (the Marquis of Tweeddale): I beg to second that.

The CHAIRMAN: If any shareholder desires to put any questions I shall be very glad to hear them.

Mr. LINDSAY NICHOLSON: I think we may well congratulate you, sir, on the results of the past half year's working. I think it looks as if the depression culminated last year; and with the revival of trade, with the improvement in metals, and the revival in the shipping interest, we have, I think, every prospect of having good returns in the present year. Let us hope that the past was the worst. When you proceed to reply to the questions, I should like to ask you, as one interested in the matter, whether there is a prospect of the cable being duplicated to the Philippines—a very important Spanish possession. I would ask you to make a memorandum for reply later on. Having said that, I should like to make a few remarks rather personal to you, Sir John Pender, than otherwise. I believe every shareholder in this room will join with me in cordially congratulating you upon the honours that have been conferred upon you (cheers). The electric telegraph and electricity are supposed to annihilate time and space, but we cannot forget that for more than 30 years you have, wherever the telegraph or electricity is concerned, been well to the front. It is for that reason, I am sure, that I shall be expressing the feeling of those in this room in cordially congratulating you. Though so much has been said about the Colonies and federation, I know nothing more calculated to encourage that federation than those little cables which we see connecting the mother country with all the countries of the world. At a time when all the Jubilee honours were being lavishly given away, I am confident that many of the shareholders of the Company would have felt no surprise if the highest honours had been conferred upon their Chairman, and I can only express a hope—and I am sure I express it in the name of the shareholders—that your present honours are but an instalment of future ones, and that you may long live to preside over this great Company, which you and your colleagues have done so much to benefit. I should like, in conclusion, to say that I will propose, as a rider to the report being received and adopted, the following words:—

"*And the shareholders of the Eastern Telegraph Company tender to Sir John Pender, K.C.M.G., their cordial congratulations on the recent honours conferred on him by Her Majesty as some recognition of his services to Imperial and Colonial interests.*"

Dr. WALLER: Sir John Pender and Gentlemen—A very pleasing and a very gratifying duty devolves upon me, and that is to second the very admirable observations made by the gentleman who has so well discharged the duty of expressing all our feelings of pleasure at the honours conferred on you. Talking of honours, I believe it confers no greater honour on you in the public estimation than you already enjoyed; but of one thing I am perfectly certain—that it in no way raises the estimation in which you are held by the shareholders of this Company, whose interests you have ever attended to with unwearying, unceasing vigilance and intelligence. We all owe you a great debt. I am an old shareholder, and remember many years of this Company, and I am able to say, what I am sure every one who hears me will concur in, that much of the prosperity of the Company is due to your great intelligence and industry. Sir, I will take leave to say this—that in the cordial wish that was made, that you may long live to enjoy the honours that have been conferred upon you, I beg to acquiesce most earnestly, and if it is the pleasure of those who know what merit is and how to reward it to give you still greater honours, believe me there are none who will more cordially rejoice than the shareholders of the Eastern Company.

The motion, on being put to the meeting, was carried unanimously.

The CHAIRMAN: Now, gentlemen, I can return you my most warm and hearty thanks, and let me assure you of this, that much as I appreciate the honour which has been conferred upon me by the Queen, I may say I appreciate more the honour which you do me in showing, not only now, but in

Digitized by Google

long years past, the most perfect confidence in me as your Chairman. Were I to go back, and give you a history of submarine telegraphy, I should require to introduce a great many names—of men you see sitting at this table, who have been associated with me. I have been more or less their mouthpiece, but their minds have always been at my disposal whenever great judgment was required. I will, however, mention one name, and I think I may do that because it is so closely connected with telegraphy in its infancy. When the first cable was laid—and that is a great many years ago—there was an impression that a cable once laid was parted with for ever. My friend Sir James Anderson proved that a cable even at 2,000 fathoms depth could be repaired. From that day I said, "There is a grand future for submarine telegraphy. If we can repair the cables, there is no doubt whatever of the vast extension of this system. It will probably federalise the world in a way which no other system would ever do." I think up to this point that all these anticipations have been realised. The working of this great system is in comparatively a few hands; but the hands which began it, nearly all of them, are working to-day—at least, those who formed what was called the combination over which for some years I have presided. I now return thanks for the honour you have done me, and I can only say that I could have done little unless I had had the support, not only of my colleagues, but of the generous body of shareholders who have stood by this Company during all these long years. Now, let us come to business. Mr. Nicholson asked about the Philippine Islands. The Extension Company, of which I am president, is now in negotiation with the Spanish Government on that matter. Probably that question should be put at the meeting of the Extension Company, but I am Chairman of both companies, and I can reply to-day. We are now negotiating with the Spaniards. The Spaniards are very much bitten with telegraph extensions. They are making some proposals that would startle even Sir James Anderson. But we never throw cold water on any Government in connection with any telegraph scheme if we think it can be done with practical results. With regard to the question you have put to me I hope before long you will see it realised.

The Marquis of Tweeddale: I have the honour to move a resolution which I am sure you will all accept with pleasure. It is

"*That Sir John Pender, who now retires, be and he is hereby re-elected a Director of the Company.*"

Mr. W. Ford: It is usual on these occasions, I believe, for the election or re-election of a Director to emanate from that side of the table; but on this occasion I must deprive the gentleman on that side of the table who intended to second the resolution of the monopoly that the Board would otherwise have in connection with this proposal. The gentleman who proposed the rider to the first resolution did so in such excellent terms, so fully representative of the feelings of the shareholders, not only those present but those absent, that it is really unnecessary for me to add any words of my own. Indeed, I should be very sorry by any remarks of mine to weaken the very favourable impression created by that gentleman's observations and by those of the gentleman who followed. At the same time I do wish to mark the appreciation of the shareholders' opinion of Sir John Pender's services by the proposal now before the meeting coming from this side of the table. Gentlemen, there is probably no one in this room who has had greater experience of the ability of Sir John Pender as Chairman of this Company than I. Both on this side of the table and that I have had many opportunities of judging of his capacities and of his faithfulness to the interests of the shareholders, and I do most cordially second the wish expressed by the honourable gentlemen who have already spoken that Sir John Pender may long live to preside over the destinies of this Company, feeling that as long as he does so no effort will be wanting on his part to do the best he possibly can for us. I have great pleasure in seconding this resolution.

The Marquis of Tweeddale: You have heard the resolution, gentlemen. Those in favour will please signify the same in the usual manner. To the contrary. Carried unanimously.

The Chairman: Gentlemen, I sincerely thank you for the honour you have done me in re-electing me to my seat at the Board. It has been the hobby of my life so far, and I believe it will in the future be my hobby to serve you honestly and well. I thank you for the honour you have done me. I now beg to move—

"*That the Marquis of Tweeddale, who now retires, be and he is hereby re-elected a Director of the Company.*"

The Marquis of Tweeddale's name is so well known that I need not say one word about this motion, except that he has been from the beginning an earnest and honest worker and supporter of submarine telegraphy; and when the history of submarine telegraphy is written, Lord Tweeddale's name will stand high on the register.

Mr. G. G. Nicol: I beg to second that.

The Chairman put the motion in the usual way, and it was carried unanimously.

The Marquis of Tweeddale: I beg to thank you, gentlemen.

Mr. Ford: The resolution which I have now to propose is not a formal one, for I recognise the efficient services which have been rendered to us by our auditors. I move:—

"*That Mr. Henry Dever and the firm of Messrs. Quilter, Welton and Company be and they are hereby elected auditors of the Company for the current year, with remuneration of £100 each.*"

Mr. Starnes: I have much pleasure in seconding that.

The resolution was put to the meeting and carried unanimously.

Mr. John Newton: In moving a vote of thanks to you I am not going to throw any apple of discord into the chorus of congratulations that this meeting has indulged in, but I do think that in proposing this vote to you I am giving expression to a thought that has passed through my mind—namely, that submarine telegraphy and your association with it have not yet received the acknowledgments which they should have received. It is a singular fact that the greatest civiliser that the world has ever known has not yet been recognised in the House of Lords. We have two or three noblemen on the boards of the various companies, but not one is in the House of Lords because of his connection with telegraphy. I think if you had been occupied in the career of arms, probably some of you would have been in the House of Lords; but you have been in a more peaceful field, and the consequences are that you are left outside the door of that great chamber. I think, notwithstanding the honour that you have had conferred upon you, it is not the honour that should have been done to those connected with submarine telegraphy during the last 30 years. Having said that, I will conclude by moving a vote of thanks to you and your colleagues for the work you have done in the past half year, and I trust that the indications that you have shown will result in a 6 per cent. dividend at the termination of the financial year. I think that a 6 per cent. dividend should not excite the cupidity of the Governments of the world, so that they would try and reduce it, because it is only 5 per cent. on the ordinary capital of those who invest in the Company. I think we should be entitled to look for a 6 per cent. dividend without any Government grudging such a return considering the splendid work that we have done.

The vote was seconded by a Shareholder, who at the same time referred to the latter part of Mr. Newton's speech about a 6 per cent. dividend. He thought an instalment of the bonus might have been paid with the present dividend, as promised, he believed, by their worthy chairman at the last meeting.

The Chairman: On the last occasion we gave a bonus for the half year because it terminated the financial year, but I said we had decided in the future to pay the bonus once a year; and I shall be very much mistaken if you do not get your bonus at the end of the coming half year. If you look at my speech as a whole you will see I dealt with the question of bonus as being a yearly, and not a half-yearly matter. We could have paid ½ per cent. to-day, but the principle of paying a bonus once a year is a sound one. If, however, the shareholder chooses to tell us it is an unsound one we will argue the question with him. We are not wedded to any point. I am quite sure that the principle is sound to pay once a year. Then you know what there is to carry forward and add to the reserve fund; and in an uncertain property like this I do not think it is right to keep our exchequer bare.

Mr. Newton: A vote of thanks is proposed and seconded. Those in favour of it will signify the same in the usual way. Carried.

The Chairman: On behalf of my colleagues and myself I thank you for this renewed expression of your confidence. I thank you more from the fact that Mr. Newton has proposed this vote. There is no one who has watched more closely or critically the working of this Company than Mr. Newton. He and I have had many spars across the table. I have listened always attentively to Mr. Newton's remarks, and we have adopted from time to time his suggestions. I am always pleased to hear Mr. Newton, because I know if there is a fault in our mail he is sure to find it out, and when a word of congratulation comes from Mr. Newton it comes with double force, and is doubly appreciated, and therefore when Mr. Newton does not find fault with the bonus being paid but once a year, I am quite sure that no other shareholder need complain. I thank you for your renewed confidence, and I am quite sure that if we differ on any small point the difference will be settled if you can convince us that you are right and we are wrong. We feel, however, that we know the "ropes," as Sir James Anderson would say, better than you, and we try and pull those ropes in such a way as will always secure stability and certainty in your dividends.

The proceedings then terminated.

The Direct United States Cable Company (Limited).

The twenty-first ordinary general meeting of this Company was held at Winchester House, Old Broad-street, on Friday, the 20th inst., under the presidency of Sir John Pender, K.C.M.G.

The Acting Secretary (Mr. T. Finnis) read the notice convening the meeting and the minutes of the last meeting, which were confirmed. The report of the Directors was taken as read.

The Chairman then said: I shall make my usual remarks on the report before asking you to adopt it. The revenue for the half year to 31st December, after deducting out payments, amounted to £23,003, and the working and other expenses, including income-tax, to £15,865, leaving a balance of £7,138. (I may mention, in passing, that that balance of £7,138 to-day at the 6d. rate, compares with £51,648 net profit at the 2s. rate.) The balance of £7,138 that is left is the net profit of the half year, making with £5,004 transferred from the reserve fund account (out of the interest received on the investments) a total of £12,142, which has been appropriated to the payment of the undermentioned dividends:—Final dividend of 2s. per share for quarter ended 30th June, 1887, £6,071; interim dividend of 2s. per share for quarter ended 30th September, 1837, £6,071—total, £12,142. A further interim dividend of 2s. per share for the quarter ended 31st December last has been declared, and is payable on Tuesday next, the 24th inst. The revenue at the sixpenny rate shows an increase of £3,399 as compared with the corresponding period of 1886, when the tariff was the same; but the progressive development in the traffic carried during the first half of last year, 1887, has not been maintained. The expenses in London show a saving in the items of salaries, office expenses, and repairs, with an increase in items of stationery and rent. The total exhibits a decrease of £458 for the half year. The expenses at stations show increases in the salary and stationery items, both caused by the large traffic at the cheap rate and the additional facilities given to the public. Reductions are shown in travelling ex-

Digitized by Google

penses, repairs, and in freight. The total shows the slight increase of £130. The expenses on the whole show a reduction of £490 as compared with the corresponding period of 1886. It is very satisfactory to note that, notwithstanding the large traffic carried, and some additional outlay incurred through the action of the French Company, our total working and other expenses during the past half year were less than in any previous half year of the Company's existence. The item of cost of removing our cables and station to Halifax (which important work will be referred to presently) remains for the present in the balance-sheet. The Company's investments continue to be worth very much more than the amount of their cost to the Company. Gentlemen, I have given you some of the hard facts connected with the working of our system during the last six months. I shall now refer to matters which may interest you in our present state of low rates. Six months ago when I had the pleasure of addressing you I referred to the large development of traffic that had taken place under the sixpenny rate. I said I did not believe that rate would be a permanent one, but that while it lasted—while the development was going on—it would be a misfortune to make any change. We, however, have arrived at a position when the sixpenny rate seems to have ceased to bring about increased returns. Consequently the opinion that I expressed then as to the mode of dealing with the question I entirely endorse to-day. What I said more particularly at the last meeting was that the very large interests which the Western Union Company held in the land system in America, as also their interest in the cables, entitled them to take an active part in the settlement of this war of rates. They did take an active part in it, and they had settled the land rates in a way which I believe is now working satisfactorily, and you all know that the Western Union Company, while settling with the company which belongs to Mr. Mackay, have also secured the control of the Baltimore and Ohio telegraph system, giving them a largely increased power in working the land system of telegraphs in America. There were some negotiations in America between Mr. Gould and Mr. Mackay. They were referred to this side, but the proposals were such that they could not be entertained. The consequence was that there was no result, and we are now in the position of having been rather blamed for not agreeing at once to the proposals then made. If, however, we had accepted these proposals, we should have been positively guaranteeing a very high rate of interest to the Commercial Company; in short, it would have been giving them a very high premium for laying cables in the Atlantic when there was no real necessity whatever for them. On this point I have frequently spoken. We are in this position to-day, that we have worked for nearly two years at the sixpenny rate. We have got pretty much all the good out of it for the moment that we are likely to get, and, speaking for myself and, I believe I may say, with the full concurrence of my Board, I should be very pleased to see a conference of the different companies held to consider the question of a fair rate for the shareholders, and an equally fair and just rate for those who use the telegraphs. Some one must lead in it, and we occupy a position respecting which we may say that the Western Union not having brought about any arrangement, something should be done on this side. I speak on behalf of my Board, and also, I believe, on the part of the shareholders I am now addressing, because, I believe, every one of them would like to see better rates and dividends than we are able to pay them under the present tariff. You are aware that the other day the suit which was brought against the French Company for seceding from the "pool" terminated, at least the decision for the time was, in favour of the Anglo-American Company. That decision meant that damages to a very considerable extent were to be paid by the French Company. I never expected any other decision from a commercial jury, because it is simply common sense that men who enter into an obligation are bound to carry that obligation out. They chose to break it, and the result is that they pay the penalty. Whether the judgment will be legally sustained on appeal, I am not a lawyer and cannot give you an opinion; but I would say, and I say it to the French Board with all courtesy and respect, that I believe instead of appealing to the courts to have this decision put aside, it would be very much better, and very much more satisfactory to them in the long run, as they have already incurred very heavy responsibilities which they must pay, if they were to appeal to us to meet together to endeavour to bring about a rate that would recoup them for the work and large expense they had been at from time to time. I think that would be very much more satisfactory, and I think it is the step that the Directors would be wise, in the interests of the shareholders, and in the interests of telegraphy generally, to take. I should be very pleased to receive a communication from them to try and meet them as far as we could to bring about a satisfactory solution. I think I have now pretty well given you the position we occupy at the present time. Some one may ask me about what rate I would suggest. I am not prepared here definitely to say what the rate would be; but I think if we could maintain the traffic which we have developed at 6d. upon a 1s. tariff it would not be a burden to the telegraphing public, and it would be very much more advantageous to us. If at the end of 12 months we did not find the one shilling tariff give us proper returns, we could reconsider the question, as I think the shareholders are fully entitled to be considered in regard to all this question with a view to giving a fair dividend on the capital they have invested. A one shilling tariff, as you know, has been very often talked about. I may mention that while we were, in the late negotiations that were going on, prepared to deal with the shilling tariff, those connected with the other companies—the Commercial and French Companies—were looking to a return to the old rate of 1s. 8d. I think that for a time we may consider that that is not likely to take place, and that the lower rate is more likely to be agreed upon. I have told you something of the present position of our negotiations, and of the position we occupy in the "war" of rates. I will now refer to the alterations we have made during the last six months in our cables. We have sustained very heavy loss from our cable lying on Brown's Bank; the interruptions there have been very frequent. Out of the total breaks in the short section of cable about 75 per cent. have occurred on that Bank, and some £68,000 have been expended in repairs to this one section since it was laid down. We have now removed that portion of short cable away from Brown's Bank, and have taken it into deeper water, and consequently we may now, I believe, hope to be free from the large expenditure which we have had from year to year to undertake. Our cable being in Halifax, if the Government desire to have a cable carried to Bermuda we are quite prepared to meet their requirements. With these remarks I shall be pleased to answer any questions, and I will now propose the resolution:—"That the report of the Directors, dated the 6th January, 1888, together with the statement of accounts to the 31st December, 1887, annexed thereto, be and the same are hereby received and adopted."

Mr. Wm. Ford seconded the motion.

A Shareholder inquired if the vacant seat at the Board was to be filled up.

Mr. Griffiths congratulated the shareholders on the well earned honours which the Chairman had had conferred upon him by Her Majesty. He saw in the report that £5,000 had been paid to the Anglo-American Company under the agreement. He desired to know what the terms of the agreement were, and how long it would last. He supposed when it terminated they would have the power of renewing it. With regard to the lawsuit in France, he was glad to see that already they had a prospect of obtaining £30,000 in connection with it. He desired to know what portion of that would come to the Company under the agreement, and what portion would go to the Anglo-American Company. They might hope there were good grounds for believing that they would sustain the verdict which the jury had given.

The Chairman, in reply, said that the payment of £10,000 a year to the Anglo-American Company was a very old story. It was contracted in the early days of the Company with a view to the joint-purse agreement. When they made the agreement with the Anglo-American Company they got a very much larger percentage of the purse than was supposed by many that they were entitled to. They therefore compromised the matter, to some extent, by paying the Anglo Company £10,000 a year, the company maintaining their full 25 per cent. The £10,000 was paid in a great measure, —the Direct being a single cable company—for guaranteeing the maintenance of their revenue in the event of any interruption. That entitled them to receive for twelvemonths their full share of the "pool," and he thought up to two years a very considerable portion of it. It was paying for a guarantee rather than going to the expense of laying a second cable. With respect to the suit with the French Company, Mr. Griffiths was a good lawyer, and if he looked into the thing he would find that it was the Anglo-American Company who had raised the suit. They had got the decision, and it remained for the Direct Company to raise another suit to obtain damages if that proceeding should be considered advisable. Meantime he thought the less they said about the question the better till the money was in their hands to be divided.

Mr. Guesdon said he had not had time to go to the office to read the contract between the Company and the Anglo-American Company; but he looked on it as a most valuable arrangement for the Company, and the payment mentioned of £10,000 a-year was one that the shareholders might make with great satisfaction. If the shareholders wished to know anything about the value of such an arrangement they had better compare the price of the Direct Company's £20 shares with those of the French Company, which he believed were a mere fraction. He saw that there was a reduction of the reserve fund between 1883 and 1887. If they took that into consideration, as well as the wear and tear and depreciation of the cable during the same period of four years, it would, he feared, be found that they were sinking their capital very fast. As far as the contest with the American Cable Company was concerned he was not in a position to offer any opinion, but he did not feel sanguine upon the subject, because whatever might be the merits of the case, the sympathies of the Americans would be in favour of their own company. Reference had been made to the progress anticipated from the reduction of the tariff not being maintained, but the question was to see how far that condition of things applied to other companies, and if the contraction only applied to the Direct and Anglo-American Companies it would seem as if the American Company was gaining ground. He believed their agreement with the Anglo-American Company was for ten years.

The Chairman: I believe it is far nearer thirty years.

Mr. Guesdon said he thought they had secured a very valuable protection. It was stated that the number of Directors had been reduced. He wished to know whether it was intended to fill up the vacancy. He regarded the Directors as partners and as trustees also. He maintained that the shareholders were getting their dividends not out of profits but out of their capital, and that the Directors from the same source were receiving their fees, and if he were in order he would move a resolution on the subject.

The Chairman said that Mr. Guesdon would not be in order in doing so.

Mr. Guesdon thought that the Directors ought to sympathise with the shareholders in the present circumstances.

Mr. John Newton said he could not agree with some of the remarks which had fallen from Mr. Guesdon. He contended that the Directors were distributing to the shareholders on the present occasion nothing but their income, for the reserve fund had been accumulated in past years out of income. The money was their capital in one sense, but the income derived from it must be their revenue; and if the income they earned was not sufficient to provide for that bread and butter, he held that the bounden duty of the Directors was to distribute the reserves of previous revenues which they held. They might have paid the shareholders justly and fairly 3 per cent. instead of a paltry 2 per cent.

Digitized by Google

Mr. E. M. UNDERDOWN, Q.C.: We could do that if it were thought wise.

Mr. NEWTON knew that that was so, and the Directors, he considered, were to be blamed for not doing so. There was an enormous accumulation of reserve—nearly 27 per cent. of their capital—which had been taken from their revenue in prosperous years. If the fight had to be continued for the next two or three years no harm, he felt sure, would result in distributing £12,000 a year among the shareholders. He expressed great satisfaction at the honour which had been conferred upon the Chairman, but he maintained, as he had at another meeting, that it was not the honour which the Chairman and others connected with the cable enterprise had well deserved from statesmen and governors of this country, having regard to the marvellous benefits which telegraphy had conferred upon the world.

Mr. WEATHERLEY agreed with Mr. Guesdon's remarks concerning the Directors' fees. In view of the dividend that was being paid to the shareholders, he thought that they ought to receive some concession from the Directors. He understood that it was not the intention of the Directors to fill the vacant seat at the Board, and he presumed that if another Director were not appointed the amount of the fees would be reduced.

The CHAIRMAN, in reply, said that the reserve fund was meant especially for repairing cables, and also, if necessary, for laying a new cable. If they were at such a time as the present to trench upon the reserve fund proper to supplement their dividend, they might find if the "war" were to continue for a certain time that all their reserve fund might disappear, and their cable would be so much older, while their credit would be of a very unsatisfactory kind, and their shares would stand in the market very much as the French Company's shares now stood. He felt sure that Mr. Newton would understand that it would never do for a company like theirs, having such a property, to be without a reserve fund. He agreed with Mr. Newton that in a time like the present, when they were fighting to maintain rates and dividends, they ought to go as far as they possibly could in supplementing the dividend from the reserve fund. Therefore they took every shilling of interest that the reserve fund earned for them and applied it to supplement the shareholders' dividend. He thought that in that way they met Mr. Guesdon's views, and he believed that when Mr. Newton thought it out seriously he would admit that it met his policy as well. In Mr. Guesdon's remarks about the reserve fund he had evidently overlooked the fact that in 1884 £100,000 of debentures had been paid off. With regard to the remarks which had been made about the Directors' fees, he thought that the Directors were entitled to ask the shareholders for their sympathy. Since they took office they had built up a large reserve fund and gone on for a long time paying 5 per cent. dividends, and under the Articles of Association they could have drawn very much more than they had for their fees. They should also remember that when things were working smoothly, there was not much difficulty, but at a time like the present the Directors had to watch every turn, and they did everything they could to promote the shareholders' interests. They could have taken under the Articles of Association 33 per cent. more than they had taken for their fees, and then they would only have taken what the Directors of the old company took before the present Board assumed office. The Directors paid for the proxies which had been issued. There were 50 or 60 shareholders present, whereas there were nearly 1,500 shareholders in the Company, and he maintained that it would not be right or just that absent shareholders should have no opportunity of expressing their views. With regard to the vacant seat at the Board, that had been caused by the death of Lord Hawke, a gentleman who had been associated with them from the beginning, who was a regular attendant and a man of good judgment. When he died they thought it would not be wise to fill up his place, and the fees which he received did not go into the pockets of the other Directors, but into the exchequer of the Company. He did not say that they would not fill up the vacant seat, as it might be desirable to do so with a view to protecting the interests of the Company. In the meantime, however, they had decided not to fill up the vacant seat.

A SHAREHOLDER asked if it would be possible to take a vote on the question as to whether the vacant seat should be filled up.

The CHAIRMAN said that such a question could not be put, as it would be out of place that day.

Mr. UNDERDOWN observed that the Directors had a right to fill up casual vacancies at the Board.

Mr. NEWTON maintained that a recommendation could be proposed to the effect that the vacant seat at the Board should not be filled up. For his own part he would not support such a resolution. At the same time he thought that the Directors ought to be inclined to listen to suggestions on the matter. If the vacancy was filled up he thought it would be politic to appoint a younger man, so that there might be continuity on the Board.

The CHAIRMAN, in reply, said that Mr. Newton had been a regular attendant at their meetings, and his suggestions had been adopted from time to time, and when any shareholder made a suggestion in a proper way, he and his colleagues gave them full consideration. They had said that they were not going to fill up the vacancy just now. With regard to the wise observation of Mr. Newton, if it was filled up it would be filled up by a younger man probably than any present member of the Board.

Mr. GUESDON said that if five men could not manage the Company fifty could not.

The CHAIRMAN admitted that two or three men might just as well manage as a dozen, but that was not the view that was entertained in the present day. What was wanted now was representation, and the Board of the Company was very representative.

He then put the motion, and declared it carried, afterwards thanking Mr. Griffiths and Mr. Newton for their kind observations respecting the honours which had been conferred upon him.

On the motion of Mr. GRIFFITHS, seconded by Mr. WEATHERLEY, a hearty vote of thanks was passed to the Chairman and Directors for their management of the Company's affairs for the past half year.

The CHAIRMAN, in acknowledging the vote, said the shareholders might rest assured that while they had the conduct of the affairs of the Company they would act in such a way as to secure the confidence and support of the shareholders.

The proceedings then terminated.

CITY NOTES, &c.

THE ANGLO-AMERICAN TELEGRAPH COMPANY.—At a meeting of the Board of Directors of the Anglo-American Telegraph Company, held 20th January, it was resolved to recommend to the proprietors at the next half-yearly general meeting of the company, to be held on the 3rd February next, the declaration of the following dividends:—1. A balance dividend of 10s per cent. upon the ordinary consolidated stock for the year ended 31st December, 1887. 2. A balance dividend of 20s. per cent. upon the preferred stock for the year ended 31st December, 1887. Both payable on the 4th February next, less income-tax, to the stockholders registered on the books of the company on the 16th inst. After paying the foregoing dividends, there will be an estimated balance of £2,300 to be carried forward to the next account. The above dividends, together with those already paid, will amount to £1. 7s. 6d. per cent. on the ordinary consolidated stock, and £2. 15s. per cent. on the preferred stock for the year 1887. The register of transfers will be closed from 20th January to the 3rd February, both days inclusive.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—Mr. W. J. Andrews has been elected chairman of this company, in place of Sir Henry Drummond Wolff, who has resigned his seat at the Board. The directors have elected Lord Richard Howe Browne to fill the vacant seat at the Board.

ALTERATION OF TELEGRAPH TARIFF TO TURKEY.—The Eastern Telegraph Company notifies that on and after 1st February the rates for telegrams to Turkey, *viâ* Gibraltar, Malta and Zante, will be reduced from 10d. to 7d. per word, being the same charge as by the Government land lines. The company suggests that telegrams for Turkey should be handed in at its own stations, 11, Old Broad-street; 41, Parliament-street; or 37, Holborn Viaduct. When sent from postal offices they should be marked "*Viâ* Eastern."

AWARDS.—Messrs. Woodhouse and Rawson have been awarded a gold medal at the Saltaire, and a bronze medal at the Newcastle Exhibitions.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 507.—Vol. XX. FRIDAY, FEBRUARY 3, 1888. Price 4d.

NOTES.

The sudden rise in the price of telephone shares since Mr. Raikes' speech of last Friday, is, perhaps, not wholly to be regretted, if it convince the Postmaster-General of the public belief and desire that the telephone shall be put on the same footing as the telegraph. We have commented on this subject at length in our leading columns; and we have only to reiterate here that, as an expression of opinion, the Postmaster-General's words were worth noticing; but they afford not the least justification for assuming that the Post Office is going to take over the telephones as it did the telegraphs. The contradiction which appeared in the *Daily News* on Tuesday, although made probably without authority, was substantially correct.

We learn that it is proposed to have a conference at which all the Atlantic Telegraph Companies will be represented, with the view to the adoption of a uniform tariff. A shilling rate seems to be the most generally approved; but so far the matter has not been discussed.

In our leading article we have referred to the probable necessity for expending considerable sums on the reorganisation of the telephone system of wires in our large towns, notably in the metropolis. To what extent this may be thought desirable will be gathered from an article on the subject by Mr. Walker Moseley, the first portion of which we print in another column. Without binding ourselves to Mr. Moseley's plan, still less to the arguments by which he endeavours to show the necessity for its adoption as an independent system, we think it sufficiently evident that to meet the future needs of the telephone service some systematic method for extending operations will have to be devised, either entirely new or connected with the existing system.

Our New York correspondent's letter this week indicates that the infliction of capital punishment by electricity has been taken up in the States with greater seriousness than we had imagined, and in quarters where we should have expected a keener sense of the fitness of things. One of the Reports declares that "electricity is the most potent engine of death at present known." A more infelicitous description with which to label electricity at the present moment could hardly have been chosen. Without wishing them any harm, we venture to hope that the next man or woman any of the framers of this Report may have the misfortune to kill in the course of their legitimate business will be described as having been "executed" by Messrs. So-and-so, the eminent firm of Electrical Engineers. This might have the effect of bringing them to their senses.

Some interesting figures relating to the destruction of theatres by fire were given by Mr. W. Emden at the Society of Arts last Friday. The list is a very heavy and alarming one. It is satisfactory to notice that only two lives have been lost in fires caused by the electric light, and that only on this occasion was the theatre destroyed. In the other cases the fire was observed and extinguished. One, at least, of the instances cited was due to an accident with the arc lights during the building of the theatre, when no extra precautions had been taken.

The discussion on Mr. Cockburn's paper on safety fuses at the meeting of the Society of Telegraph-Engineers on Thursday last was of a thoroughly practical character, and it is a matter for congratulation that the subject should have been so well thrashed out. At the same time we fully endorse the remark of Mr. Crompton—which was also backed up by Messrs. Mordey and Esson—that a vast amount of nonsense has been talked (elsewhere) about the precautions against danger of fire from electric lighting. We would not say a word to discourage the adoption of all reasonable precautions in every installation; but, as we have already had occasion to assert, the continual and unnecessary discussion of these questions has had the effect in some quarters of shaking public confidence in electric light. It is for this reason that we have always deprecated the want of harmony which exists between the Committee of the Society and certain of the Fire Insurance Offices. As a natural consequence we have just learnt that one of the Insurance Companies is preparing an independent set of rules on its own account. We shall therefore shortly have three separate sets of regulations in the field.

Prof. Silvanus P. Thompson is of opinion that an important consideration affecting the choice of metal for use in lightning conductors has hitherto been overlooked. In a paper read before the Physical Society on Saturday last he set forth the view that the temperature of fusion should be taken as a factor in estimating the efficiency of a conductor. It is, at least, undeniable that if there existed two metals alike in all other respects, that metal which had the highest melting

Digitized by Google

point would be most suitable for the purpose. The question then arises whether any cases have been recorded in which a lightning rod properly constructed has been fused. If so, it would become necessary to consider whether it were more economical to increase the sectional area of the conductor or to employ some other less fusible metal. It is from this point of view that Prof. THOMPSON speaks of "the price of the factor of safety in lightning conductors."

IN the discussion which followed the reading of the paper some doubt was expressed as to whether a case of fusion has ever been known to occur with a conductor properly connected to earth. But be this as it may we think it will be admitted that the question raised by Prof. THOMPSON is one which should now receive the fullest consideration. Unfortunately the calculations presented with the paper were to some extent vitiated, at least in the case of iron, by the neglect of so important a factor as the coefficient of self-induction. In taking this course the author probably contemplated the use of iron only in the form of stranded wire; but, even so, it appears by no means certain that the self-induction coefficient is negligible in comparing iron with copper. On the other hand, it would certainly be very difficult, if not impossible, to embody the influence of self-induction in a general formula for the heating effect.

THIS point is all the more important because, taking Prof. THOMPSON'S interesting table as it stands and neglecting self-induction, we find that if a copper conductor with a given factor of safety costs £100, we may obtain the same degree of safety with an iron conductor costing only £21. 9s., so that the argument in favour of iron is a very practical one. A conductor of lead or tin would prove an expensive luxury, costing more than six times as much as copper, while if any one happens to have a whim for using platinum he will be interested to learn that the relative cost would amount, at the present market value of that metal, to over £1,620,000—a figure which may perhaps be considered prohibitive.

PROF. S. P. THOMPSON is not the only authority who is inclined to advocate a return to the use of iron for lightning rods. Dr. L. WEBER, in a work recently published in Germany, under the title of "Information and Advice relating to the erection of Lightning-Conductors," not only recommends the use of iron in preference to copper, but actually goes so far as to state explicitly that a solid rod is better than a stranded wire cable of equal cross section. We feel sure that Prof. THOMPSON would not countenance this advice, and it seems strange that in a country like Germany, where lightning is much more destructive than with us, it should have been allowed to pass—so far as we know—without further protest.

IT is a curious fact that the generally received opinion as to the area of the zone over which a given conductor is capable of affording protection has undergone a continuous diminution from the time of GAY-LUSSAC downwards. In a famous report drawn up by GAY-LUSSAC for the French Academy, in 1823, it was held that a conductor 100 metres in height would afford protection over a *cylindrical* space having a radius of 200 metres. Later opinions as to the figure of the protected space have oscillated between the cylindrical and the conical form; but theoretically there can, we think, be little doubt that the true figure is conical. The following table gives some of the views held by the leading authorities on this subject, the height of the rod being taken as unity in each case :—

Name.	Figure.	Radius of Protected Area at Ground Level. Height of Rod = 1.	Date.
Gay-Lussac	Cylinder	2·00	1823
De Fonvielle	Cone	2·00	1874
Paris Commission	Cone	1·75	1875
Chapman	Cylinder	1·00	1875
Adams	Cone	1·00	1881
Preece	Special Cone	1·00	1881
Melsens	Cone	0·50	1884

Mr. PREECE'S protected zone is described by a cone the sides of which are concave, and are marked out in section by an arc of 90° described from a point on either side at the level of the top of the rod, and distant from it by its own length. It must, however, be admitted that, whatever may be the true theory, such calculations as these have only a slender value in practical application. The actual extent of the protected zone must largely depend on the size, shape and structure of surrounding buildings. That the smaller values are more likely to be generally true than the larger is proved by more than one recorded instance, in which lightning has struck the deck of a ship when the conductor on the mast-head has been in perfectly good condition.

WE commend Mr. FLOOD PAGE'S letter in *The Times* of Tuesday not only to Members of Parliament, but to members of the electric lighting profession generally. It is remarkable that an appeal to the leading newspaper against the legal disabilities imposed by the Act of 1882 should come from the secretary of a single electric lighting company. This is the time for united action; and if electrical engineers have not yet made up their minds to formally associate under one title, they at least ought to combine in action for an object common to them all.

AN interesting experiment in long-distance telephony has just been carried out in France. It was some time ago decided to connect Paris with Marseilles by telephone, the distance being over 500 miles. Seeing that no telephone line of this length as yet exists in Europe, the authorities were anxious to make some practical experiments upon as large a scale as possible before undertaking the work. For this purpose, with the co-operation of the Belgians, a special circuit was made up of existing bronze wires, as follows :—Antwerp to Brussels, Brussels to Paris, Paris back to Brussels by the second line, *viâ* Momignies, Brussels to Verviers, the total length between the terminal stations by this route being about 620 miles. The results are said to have been of a highly satisfactory character,

Digitized by Google

the articulation being as clear and distinct as that between Brussels and Paris.

SPEAKING of long-distance telephony, there is a paper in the *Philosophical Magazine* this month which no one interested in this subject should omit to read. It is unhappily true that there are very few men engaged in practical work who will be able to follow Mr. OLIVER HEAVISIDE'S abstruse exposition of the principles of electro-magnetic induction; but every one can recognise the importance of a statement like the following, coming as it does from one of the first living authorities in the mathematical theory of electricity. On page 137, Mr. HEAVISIDE says, "It seems to be imagined that self-induction is harmful to long-distance telephony. The precise contrary is the case. It is the very life and soul of it. . . . I have proved this in considerable detail; but they will not believe it." The proof referred to may be studied in detail in *The Electrician*, Vols. XVIII. and XIX.; but, unfortunately, it is not in such a form that he who runs may read. It would, perhaps, be a good thing, if we were some day to publish a gloss upon these papers adapted to the understanding of the ordinary electrical engineer. This is not, however, the only passage of general interest in Mr. HEAVISIDE'S paper; many of our readers will be surprised to learn (the remark is quoted from MAXWELL), that "for anything we know to the contrary, the velocity of electricity *in a wire conveying a current* may be only one inch or so in an hour." Later on we are introduced to a conductor "having a time constant of one fortnight." These little pleasantries are continuously cropping up in the most unexpected places in the writings of this learned author, and it seems a pity that they should be lost in a wilderness of quaternions.

ANXIETY about sea-coast defences is not confined to this country. An American scientific contemporary, commenting on the undefended condition of New York, makes the following characteristic onslaught on a recent experiment conducted by Major KING, which we described at the time:—"Is it not a scathing comment upon this scandalous condition of affairs that the commandant of our principal torpedo station at one of the principal forts supposed to defend New York can find no better use for the war material in his charge than to wind his worthless old cannons with worthless old torpedo cable, and try experiments in electro-magnetism?" Really our American brethren might take consolation from ourselves. Worthless stores may be put to far worse purposes than experiments in electro-magnetism; and with us they are apt to lie completely idle till the serious experiment of warfare has demonstrated their worthlessness for any purposes whatsoever.

THE "proverbial uncertainty of the electric light"—as the gas journals say—is aptly illustrated by the following little incident, which is, we believe, authentic. A lamp had been hung from the kitchen ceiling by flexible leads; so when the housemaid wanted a light in the cellar she did not hesitate to cut off the lamp and hang it from the bell-wire. Then she said she "didn't never believe in these here new-fangled notions."

Club Lighting.—Specifications have been issued for the electric lighting of St. Stephen's Club.

Copper.—The price of copper has slightly risen during the week, Chili bars being quoted yesterday at £75. 5s. to £75. 15s.

Syra.—According to a French Consular Report, it is intended to provide an installation of electric light for the harbour of Syra.

"L'Electrotherapie."—A new monthly journal devoted to medical electricity is about to appear in Paris, under the title of *L'Electrothérapie*. It is to be edited by Dr. Danior.

The Electric Light and the Theatres of Madrid.—The *Dia* states that the contract has been signed by the firm of Bloss of Madrid for the immediate lighting by electricity of the Principe Alfonso Theatre.

The Treatment of Sewage by Electricity.—The Metropolitan Board of Works, at their meeting last Friday, resolved to permit Mr. W. Webster, jun., to carry out an experiment on the sewage of Crossness, with his system of electrical purification. For this purpose he is to have the use of one of the tanks; the trials to be made at Mr. Webster's own expense, and under the supervision of the officers of the Board.

Incandescent Lamps.—M. Hees has carried out some experiments in order to determine the effect of variation in the degree of the vacuum in an incandescent lamp upon its photometric power. On gradually increasing the pressure no effect was perceptible up to a vacuum corresponding to 2 mm. of mercury, but from this point the light rapidly fell off, and at 6 mm. of mercury it had fallen to only one-third of its original value.

Trade Catalogue.—The United Electrical Engineering Company, of 36, Albert Embankment, send us a copy of their newly-issued catalogue of electrical supplies. This is one of the most complete lists of electrical requirements which we have come across. Considerable care has evidently been devoted to the book, and the tabulated information concerning dynamos, accumulators, &c., will be found very useful to intending buyers.

"Fifty Years' Progress in Telegraphy."—Under the auspices of the Sunday Lecture Society, Mr. William Lant Carpenter, B.A., B.Sc., delivered a lecture on Sunday afternoon last, at St. George's Hall, Langham-place, on "The Electric Telegraph; its Past Half Century, and its Recent Progress." There was a numerous attendance, and the lecture, which was illustrated with experiments and diagrams shown by means of the oxy-hydrogen lantern, was listened to with great interest.

The Deposition of Aluminium.—Aluminium is one of the most difficult and uncertain of metals to deposit electrolytically. The following recipe is given by M. Herman Reinbold, who states that it furnishes excellent results:—50 parts by weight of alum are dissolved in 300 of water, and to this is added 10 parts of aluminium chloride. The solution is heated to 200°F., and when cold 39 parts of cyanide of potassium are added. A feeble current should be used.

The North Metropolitan Tramways.—At the general meeting of the shareholders of the North Metropolitan Tramways Company on Wednesday, the chairman (Mr. George Richardson) stated that extensive experiments were being made in connection with the use of electricity on their system. He could not say whether the experiments would prove successful or not, but the company incurred no risk in connection with them; and if it could be shown in due course that electricity could be profitably used on their lines, they would derive the advantage of it.

Digitized by Google

The Lighting of the Cardiff Docks.—The arrangements for lighting these docks by electricity are nearly completed. A powerful Brush dynamo machine has been placed near the Bute Graving Dock, and this will supply current for a number of Brush lamps placed at the entrances and round the basins of each dock. The entire Roath Basin will be lighted by electricity. The upper portion of the docks will still be lighted by gas from the Bute Gasworks, but this system will be abandoned after a time, and another dynamo machine placed at the upper end of the dock. For the lighting of the entrances, basins and part of the new docks nearly 100 large lamps will be used.

Spanish Tender for Electric Light.—The directors of the Madrid Mercantile Club (Circulo de la Union Mercantil) invite proposals for lighting the club by electricity. The conditions, which are published in the *Comercio Espanol*, of Saturday last, provide for the installation of three arc lights, and 160 to 200 lamps of 16 candles. As the club premises have not a convenient place for installation, the machinery and apparatus will have to be located in a separate building. Proposals drawn up in accordance with the detailed requirements published in the Madrid paper must be sent to the president of the club before the 1st of March next. The duration of the contract, the daily supply of light, and the amount of guarantee to be deposited by the contractor are all subject to arrangement.

The Post Office and the Telephone Companies.—On Friday last the Postmaster-General, in the course of a reply to the Wolverhampton Chamber of Commerce on the subject of postal and telephone charges, remarked that—

"Respecting telephones, it was unsatisfactory that the Government had to compete with private firms, and before long the system must be taken up by the Government, and telephones placed on the same footing as telegraphs, and be controlled altogether by the Government."

On Tuesday the following paragraph appeared in the *Daily News*, but we believe in no other paper:—

"We are officially informed by the Postmaster-General that the statement that he had announced the intention of the Government to acquire the telephones is erroneous. Mr. Raikes has announced no such intention."

Our own views on this subject are fully stated in other columns of the present issue.

Dynamicables and Electro-Harmonics.—The dinner of the Dynamicables, which was held at St. James's Hall on Friday last, was largely attended, and proved to be a very enjoyable gathering. The post-prandial proceedings were cut shorter than usual by the announcement of an invitation from the Electro-Harmonic Society. The Dynamicables were invited to attend the Society's Smoking Concert, which was held the same evening in the same building. The concert proved to be one of the most successful which the society has ever given, and the attendance was both large and enthusiastic. The programme consisted chiefly of old English songs, together with a judicious selection of modern ballads of a comic cast. We heartily congratulate the committees of each of the clubs concerned on the success of Friday night's proceedings.

Electrical Method of Rendering Visible the Form of Vibrating Strings.—Herr J. Puling, of Vienna, has devised an extremely ingenious method of rendering visible the form of a stretched string set in vibration. One of its extremities is attached to the prong of a tuning-fork, which is kept in motion by an electro-magnet contact breaker, and which gives a definite note, the pitch of which is carefully determined. The vibrating string is lighted up by a vacuum tube connected with a Ruhmkorff coil, the rate of discharge through the tube being alterable at will, and when this is made equal to or some aliquot multiple of the number of vibrations made by the string, the latter is only illumined when occupying some one definite position, and, owing to the persistence of its image on the retina, it appears as if at rest. In this way the form assumed by the string and the positions of the modes and ventrical segments are rendered clearly visible.

Electric Traction on the Metropolitan Railway.—As already announced, in the report of the directors of the Metropolitan Railway Company submitted at the shareholders' meeting last Friday they stated that negotiations with the Electric Traction Company had enabled them to conclude an arrangement whereby that company had undertaken to construct, at their own expense, for experimental running upon a section of the railway outside the circle, a locomotive of the same power as the company's present steam locomotives, the directors giving them the necessary facilities for such experimental working. In reply to a question on the subject, the chairman (Sir E. W. Watkin, Bart., M.P.) stated that they were doing all they could to assist in making practical experiments with regard to electric locomotives. He could not say whether the matter would succeed or not; but the directors thought that if their railway could be worked without the emission of smoke and steam—that was to say, if their tunnels could be made as pure as the air in the street above them—it would be a very great advantage.

The Electric Light at Exeter.—The *Western Morning News* says that "the public at Exeter have been trifled with over the electric light. Private speculators came to the city some weeks ago, and obtained the sanction of the council to erect poles in the city. It was announced, on the authority of the local agent, that the streets were to be lit by electricity for a month. But instead of that, a number of tradesmen were got to subscribe for lamps in connection with their establishments, and the poles were used to convey the current for that purpose, whilst the public, in whose behalf the poles were presumably erected, were neglected. At last, however, it seems that the streets are no longer to be disfigured and the kerbing broken up through the erection of these poles to no purpose, for several arc lamps were hung yesterday with a view to lighting the streets. This may be some compensation for the delay, disappointment, and inconvenience which have been caused. To the electric light, as exhibited since Christmas, citizens of Exeter do not, however, as a whole take kindly, the principal objection being that the light is too glaring for the eyes. This is possibly the fault of the globes."

The Commissioners of Sewers of the City of London and Electric Lighting.—At a recent meeting of the Commissioners of Sewers of the City of London, the Remembrancer (Mr. Goldney) made a statement respecting an application of the South Metropolitan Electric Supply Company for a Provisional Order to light a large part of the eastern and western ends of the City. He said that a part of the area would comprise a portion of the district which he understood the Commissioners had before them with reference to the Brush Company. The Provisional Order, if obtained, would give the supplying company a monopoly of the ground specified; and if the Commissioners determined to give the lighting to the Brush Company, they must oppose it. It would be hardly possible for the two companies to occupy the same area.—Mr. Ashby thought they ought to let the companies do as they pleased.—Mr. Bell expressed surprise that the last speaker should object to the Commissioners giving themselves *locus standi.* While they were

Digitized by Google

on the point of coming to a conclusion, another company was seeking to obtain a monopoly and shut them out. The company referred to wanted to put inumerable wires overhead. He moved that instructions be given to oppose the Bill, and this was agreed to.

An Enticing Offer.—Mr. F. H. Bowman has written to the *Bradford Observer* as follows:—"I see that a consultation between the Corporation and their electrical engineer, along with Dr. Hopkinson, F.R.S., is being held to-day to fix on the general scheme for the lighting of the town, and I trust, therefore, that before long something will be done. Since I last wrote to you, in consultation with our engineer, I have formulated a plan by means of which Bradford can be supplied with electricity without any cost for the current itself—a plan which I am perfectly certain will work, and which will secure all the special points which Mr. Priestman wishes to obtain, viz., that the current will be available at any time, night or day, and can be supplied to the customers either at a high or low pressure (in tension or quantity). This system, if applied, will enable each customer to select how he will receive his current, depending on the work which he requires from it, and it can be supplied either by measure or time. If this scheme is adopted, the fact that the current will cost nothing to generate it, and the first cost of the plant being reduced to the minimum, will render it possible to supply Bradford with a large quantity of electricity for all purposes at as little cost as if there was a large waterfall available in the neighbourhood."

Telephonic Concert at Stafford.—On Tuesday evening last, the National Telephone Company (Limited) gave an interesting telephonic concert at the residence of Mr. W. O. Rooper, at Stafford, at which over sixty of the leading residents of the district were present. The music, both vocal and instrumental, was provided by Dr. E. W. Taylor, at his residence, Wolverhampton-road. At Mr. Rooper's residence a large room had been fitted up with a number of "receivers" attached to the tables at which the company sat. Before commencing, Mr. Alfred L. E. Drummond, the local manager of the Telephone Company, in the course of a short speech, explained that what he wished to demonstrate that evening was that the telephone, in addition to being useful for ordinary conversations, was quite capable of being used for the transmission of music, and in fact for any variety of sounds. He also explained that the entire music was transmitted over only one line of wires, and was distributed through over thirty receivers in the concert room, this being a very severe test. The audience were quite enthusiastic at the conclusion of the concert, when "God save the Queen" was sung. The musical performers and the National Telephone Company, through Mr. Drummond, were thanked for the trouble they had taken and for the interesting entertainment provided.

The Western Union Telegraph Company and the Mexican System.—The Mexican papers now coming to hand are a little exercised about a rumour to the effect that a representative of the Western Union has arrived in Mexico for the purpose of proposing the purchase of the telegraph lines owned by the Government. The sway exercised by the Western Union over the commercial and journalistic interests of the United States is so complete that many American statesmen think that the telegraph lines of the United States should be taken charge of by the Government, and the *Two Republics* suggests that before considering any proposition from the Western Union, the company's past record and present position should be investigated. The paper quoted is of opinion that greater efficiency might be attained without a transfer of the lines from the Government to the corporation named; indeed, it is thought likely that an improvement of the federal system will be shortly brought about by the competition of the rivals which serve most of the principal cities of Mexico. All the railroads in Mexico own and operate telegraph lines, and besides these there are telegraph companies competing with the Government. At present there is no telegraph monopoly in Mexico, and it is argued that the interests of the public would be best served by opposing any attempt of one company to obtain entire control.

The National Telephone Company's Stand at the Dundee Trade Exhibition.—This exhibit includes specimens of the instrument and apparatus in practical use, from the subscribers' instrument to the switch table (for connecting subscribers together), attended by a trained operator. The stand is in connection with the company's Dundee exchanges, and from it conversation can be held with subscribers in Dundee, Broughty Ferry, Newport, Tayport, Monifieth, Perth, Forfar, Arbroath, Kirkcaldy, Dunfermline, Stirling, Bridge of Allan, Alloa, Falkirk, and Grangemouth, &c. Visitors to the Exhibition have heard by telephone the orchestra at Her Majesty's Theatre, and subscribers listen at their own fireside to the concerts taking place in the Exhibition. The call office attached to the stall has been largely taken advantage of, not only by subscribers, but also by the Exhibition authorities and the general public. Conversations to and from the Exhibition pass over the wires stretched on the standards at each end of the stall, and these wires and standards are typical of the system of overhouse construction introduced by Mr. A. R. Bennett, the company's general manager. The wire used in towns is of silicious bronze. On the table specimens of the various kinds and gauges of bronze copper and iron wire adapted to particular uses are shown. There is also a specimen of the submarine telephonic cable which crosses underneath the Tay, and of other cables in use in the district. Insulators of various patterns are shown. Of the apparatus various makes of magneto bells are prominent. These are fitted with the circuit key, adapting them for use with Mann's circuit wire system, which was first brought out in Dundee. This circuit wire system enables subscribers to speak to the operators independently of their direct wires, and is of the greatest advantage in securing promptness and certainty in the connection of subscriber to subscriber. Mr. Bennett's translator for enabling single wires in towns to be connected to inter-town loop wires without destroying the efficacy of the loops is also shown. An apparatus for automatically counting the number of messages passing through telephone exchanges (designed by Mr. Miller, manager of the company in Dundee) is shown in working order. An intermediate switch now extensively used by the National and other companies, a new form of circuit key, a disconnection signal for use on trunk lines, a table telephone set, and an arrangement to enable each operator in the telephone exchange to communicate instantly with any other operator without the aid of a third operator, for rendering the connection of subscribers more expeditious, all designed by Mr. Miller, are also to be seen. A pole changer, designed by Messrs. Brown and Jamieson for the purpose of ringing subscribers by the mere depression of a key by the operators, is worthy of notice. It forms an excellent "shocking" machine, and in this capacity has afforded much amusement to visitors, besides performing the real work required of it. A fire brigade alarm for fixture at street corners should also be mentioned. The breaking of the glass front instantly sounds an alarm at the fire station, and indicates whence the signal came. The receipt of the signal at the fire station is acknowledged by the word "coming" appearing on the face

Digitized by Google

of the alarm in the street. The various sundries of telephone work, such as batteries, lightning arrestors, switches, indicators, &c., go to make up a highly interesting exhibit. A number of the appliances are made in the company's own workshops in Dundee and Edinburgh.

The St. James's Vestry and Electric Lighting.—The Lighting Committee of the Vestry of St. James's, Westminster, have had under their consideration the draft South Metropolitan Electric Lighting Order. While keeping in view the interests of the general body of probable consumers of electricity, and the rights of the public as preserved by the Vestry, the committee have paid particular attention to certain undue restrictions which they consider would affect prejudicially the interests of the consumers. The committee have recently reported at considerable length on the subject; and they state that some of the conditions which the undertakers seek to attach to a right to require a supply of electricity are "so onerous as to be almost prohibitory in character." For example, they propose that they shall not be compelled to supply electricity to any private consumer in a street where a main has not been laid, unless six or more persons agree to pay, for a period of three years, such a sum as will represent 20 per cent. per annum upon the cost of furnishing the supply. Another proposal is that a would-be consumer, after a main has been brought within 25 yards of his premises, must agree to pay a similar sum, representing 20 per cent., for two years. The committee say that if the company attempt to enforce such conditions as these to any large extent, the general introduction of electricity, for the purpose either of light or power, will be "relegated to the very distant future." The committee also think it their duty to point out that if, through the introduction of electricity, the large consumers withdraw, the gas mains will continue to be charged as at present; and it is evident that the area and cost of distribution would be proportionately increased as the length of unprofitable mains is extended. In this case, the price of gas would probably rise, and the increased cost fall upon the smaller and poorer consumers. Indeed, observe the committee, it is possible for the poorer locality to be deprived both of gas and electricity, for, under the provisions of the Electric Lighting Act, the Board of Trade may relieve a gas company of their obligation to supply gas in an area sufficiently supplied with the electric light, if gas lighting has become unremunerative; yet at the same time the price of electric lighting might be too great for small householders. The committee also consider that the capital of the undertakers—£250,000—is utterly inadequate to carry out the obligations of the order in so extended an area as that proposed; and they view with great disfavour any attempt to obtain a concession for the supply of electricity in a large district with insufficient capital, with the evident intention of subdividing it into sections each to be "floated" by the original undertakers. Many clauses are objected to by the committee; amongst others, Clause 43, by which the undertakers seek to impose a limit of 50 yards as the maximum distance of a public lamp from a main. The committee point out that gas companies have to supply such lamps at 75 yards distance; and the same distance should, they think, be fixed for lamps lighted by electricity. Copies of the report have been sent to the Board of Trade, to the Metropolitan Board of Works, and to the Parliamentary agents for the order.

Lecture on Electricity as a Motive Power.—Under the auspices of the Free Public Library Committee of the Leeds Corporation, a lecture was recently delivered by Prof. Stroud, of the Yorkshire College, on "Electricity as a Motive Power." Prof. Stroud, whose lecture was illustrated by means of the oxy-hydrogen light, and by interesting and very successful experiments, explained the various forms of motors, and remarked that at the present moment electricity could be produced by means of a dynamo machine at a cost somewhat under one penny per horse-power per hour, that being a reduction in the cost at which electrical currents were produced of one-fortieth as compared with twenty years ago. It seemed to him that electricity was specially applicable to locomotives. In the first place, electricity possessed the unique advantage of not requiring the motive agent to move with the conveyance. The horse preceded the carriage it was drawing—the locomotive the train. The average weight of a locomotive was about that of six carriages filled with people; ten carriages comprised an ordinary train, hence the presence of the locomotive added at least 50 per cent. to the horse power required to propel the train. Indeed, when they contemplated a steam engine the wonder was, not that it could draw carriages, but that it could move itself. But there was a more serious objection to the engines than that. As they had to pass over every part of the line, that necessitated the whole line and all the bridges being made many times as strong, and many times as costly, and the expense of maintenance was considerably greater than if there were no locomotive. As the traction was applied only to one pair of wheels, it was not possible to make the engine much lighter; otherwise the adhesion with the rails would not be sufficient to enable the locomotive to draw the train. The use of electricity would enable the power to be employed by every pair of wheels, the result of which would be, first, that it would save the permanent way from wear and tear; and second, it would enable the train to go round curves and along the line at very much greater speed, and with only a fraction of the present jolting. Possibly double the present speed would not be considered excessive for an electrical train. Furthermore, a train would be able to get up speed in a few seconds, instead of as many minutes. This followed from the principle of continuous brakes. With an ordinary train of ten carriages it took one minute to attain a speed of 30 miles per hour. If this motion was accelerated more rapidly the wheels would slip. But if power were applied to every wheel it would attain that velocity in six seconds, and with no more jerk than was now felt when a continuous brake was applied. If there were power enough a train could go up a steep hill, instead of being confined, as practically they were, to an incline of 1 in 80. An ordinary train slipped down an incline of 1 in 50 when the locomotive alone was braked. But when all the wheels were braked the train rested on an incline of 1 in 5. With the necessary power they could ascend an incline of 1 in 5 with electrical motors. As to cost, an ordinary railway line on the level costs £5,000 per mile; whereas, when there were tunnels, bridges, and embankments to build, the cost rose to £15,000 per mile. Now, the interest on the capital outlay of a railway was usually a far more serious matter than the working expenses. With electrical locomotives going up and down hill, the original outlay would be more than halved. The mayor had remarked that he hoped it would be possible to produce electrical currents much more cheaply than they could produce them at present. There was one great discovery yet to be made. They wanted an arrangement for converting heat directly into electricity without the intervention of the steam engine. Electricians were endeavouring to solve that difficulty, and when it was solved it would mean the abolition of the steam engine at once, and the steam engine would become, in fact, a relic of antiquity.

A PROPOSED NEW PUBLIC TELEPHONE SYSTEM FOR CITIES AND LARGE TOWNS.

BY WALKER MOSELEY.

Electricians and others interested in the telephone question are aware that in three years the master patent rights expire. The telephone companies indulge in some hope that the patent rights will be renewed; but if they can make out a case in favour of renewal the twenty-second section of the 1883 Patents Act will have to be considered. It is as follows :—

COMPULSORY LICENSES.

Sec. 22. If, on the petition of any person interested, it is proved to the Board of Trade that by reason of the default of a patentee to grant licenses on reasonable terms—

(*a*) The patent is not being worked in the United Kingdom ; or,

(*b*) *The reasonable requirements of the public with respect to the invention cannot be supplied* ; or,

(*c*) Any person is prevented from working or using to the best advantage an invention of which he is possessed,

The Board may order the patentee to grant licenses on such terms as to the amount of royalties, security for payment, or otherwise, as the Board, having regard to the nature of the invention and the circumstances of the case, may deem just, and any such order may be enforced by mandamus.

If the Board should be convinced that the italicised words apply to the existing arrangements of the United Telephone Company's system, the compulsory license would be ordered in favour of any suitable applicant. But before any application of the kind would be necessary, the company must get an extension of term of patent right, and to do this they have to prove the following words of the fifth clause of the 25th section, viz., *the patentee has been inadequately remunerated.*

In any case, however, no legitimate interest can suffer from a thorough investigation at the present time into the ways and means for the immediate future of public telephony.

Four years ago the United Telephone Company sought to obtain, by a private Bill, parliamentary powers to enable them to lay wires underground or erect them overhead without asking leave of anybody. I wrote three letters on the subject, signed "Mos Legem Regit," which appeared in this journal, and either my criticism or other reasons caused them to abandon the Bill about a week or two after. The company now announce their intention to apply again for similar powers. What has transpired since then to change the situation? At their last general meeting the chairman explained how they had commenced a remodelling of their exchange system by the adoption of the American multiple switch-board. It is also well known that by the adoption of the "double-wire system" the Post Office electricians have demonstrated in Newcastle and elsewhere that the evils of induction may be quite eliminated. In New York they are so confident of the "double-wire system" that they have already spent £60,000 on the new multiple switch-board adapted to the system for the New York Central Exchange Room.

I put forward the following proposal because I think that the whole scheme would be better carried out *en bloc* than be added piecemeal to an imperfect system. In the endeavour to rivet attention, my preliminary explanation of certain details may not appear sufficient to commend the whole scheme, but as in succeeding papers I shall have to return to the salient points for closer examination and illustration of details, I trust the present sketch will meet with a certain amount of indulgence. But meanwhile I can promise that I have grappled with every practical difficulty, and I shall fearlessly challenge any criticism of the means I have devised to overcome them. I now proceed without further preface to explain the details of my method as adapted to the requirements of the Metropolitan district.

The diagram (Fig. 1) is formed to suit the geographical and commercial disposition of the various sections of London. The letters A B represent respectively the Bank and Piccadilly-circus. The straight thick line is the inmost line of route for wires leading east and west to the central exchange, to be established somewhere in the neighbourhood of Lincoln's Inn-fields or Covent Garden Market. The surrounding endless lines and the radial and rectangular lines complete a system of arterial conduits for leading wires to every part of London within an area of six miles by three. These conduits I propose to fix along the fronts of buildings and existing lines of streets as far as practicable, and as a rule at a height of about twenty-five feet from the ground. Of course, thus far the plan proposed might be rejected as commercially impracticable without obtaining certain powers by Act of Parliament; but that shall be discussed later on. It will be seen that in any area within the outer circle about four out of five of the renters would be connected with the arterial system by an aerial line not requiring *any intermediate support*, and none of them would require more than *one* intermediate support. The difficulty of obtaining way-leaves, and the hitherto serious delay in getting connected with the Exchange system would consequently disappear. The same facilities would enable any one to have a private wire at short notice. The Central Exchange I propose to be limited to five thousand renters as a maximum not likely to need extension for many years to come. For auxiliary exchanges I propose to set up one at each of the intersections on the outer circle, say 40 in all, with a capacity at the outset for about 100 or of 150 to each.

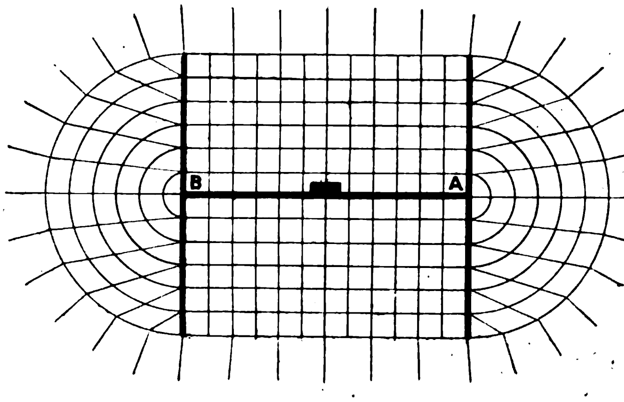

FIG. 1.

The renters connected to the Central Exchange would form a separate group from those connected to the Auxiliary Exchange, not determined by their locality, but by the frequency with which they use the telephone. A central exchange with switch-boards fitted on the multiple system would be most serviceable to renters who have most use for the telephone and whose time is most valuable. This group would pay, say, £20 per annum, but the remainder would pay only £10. It may be that the alternative could not be fairly made a matter of choice on the renters' side only, but this would be determined by considerations that would involve too much detail for present purposes. As regards "call rooms" for the use of the general public on a small fee for each conversation, it will be obvious that the system described thus far would facilitate their multiplication as required. Beyond the outer circle I propose that radiating lines of route shall be chosen for leading conduits to populous districts, and that these conduits shall be fed from aerial lines.

Before entering further into detail I will refer briefly to the advantages to be derived from the plan sketched out. Four years ago the United Telephone Company informed their shareholders at a general meeting (*Electrician*, February 23, 1884) that "if you put a telephone wire under the earth you diminish its value by fifteen times out of sixteen." The significance of this declaration lies in the fact that nothing is known now in opposition to it that was not known at the time it was uttered as the reason why the company could not consent to fall in with the public feeling against overhead wires. Public telegraphy had been carried out successfully and economically throughout Germany for *twenty years* almost entirely with underground wires, but the results of tentative telephony through underground wires were so discouraging that the principal telephone companies felt justified in condemning underground wires without ascertaining how much the failures

Digitized by Google

were due to induction and how much to leakage. Nevertheless, it may be assumed that the companies are now prepared to admit that underground wires *can* be insulated well enough to prevent serious leakage, and that by the adoption of the double-wire system—or in other words a complete metallic circuit—the evil effects of induction can be obviated. Still it is quite intelligible that from a commercial point of view (a short-sighted view, possibly) it would have been very hazardous to have incurred the great expense until it could be no longer avoided. The United Telephone Company summed up the question in a circular to their shareholders, Feb. 14, 1884, thus—"It is uncertain whether the result to telephonic communication would be so satisfactory, and certainly the cost would be so large as entirely to prevent one of the objects of the company, viz., to give a cheap telephonic communication to the whole of London." In 1880 I pointed out in the columns of *The Electrician* that good and permanent insulation was too important to let a timid temporary economy stand in the way of sound work at an adequate outlay. If, therefore, the system I have sketched out can be shown to meet the three difficulties hitherto insuperable, it will be worth while to consider carefully the principal details. The three difficulties may be briefly termed

1. To secure insulation;
2. To kill induction;
3. To install and maintain economically.

The mischievous nature of faulty insulation is now fully admitted. I myself went very fully into this subject in some papers on "Electric Bells" which appeared in the columns of *The Electrician* in 1880, and also under the head of "Fire Risks from Electric Lighting," in 1882. These considerations make it clear how much more the faults of "stray talk" on contiguous lines must be due to leakage rather than to induction. Bad insulation, everybody admits, is remediable; but induction has been generally spoken of as inevitable, and the *bête noir* of telephony. Both faults have been multiplied, as a rule, where underground wires have been used; hence the opinions and the policy of the United Telephone Company. It has been fully proved within recent years, however, that two well insulated lines running close together may be used as a complete metallic circuit without any induction from adjoining wires being observed, hence it has been assumed that nothing need prevent the immediate adoption of underground routes. But faulty insulation turns out, after all, the *real bête noir*, and the adoption of a complete metallic circuit would, *cæteris paribus*, only increase the old evil. My remedy essentially and practically is to take up and extend the method described in *The Electrician* of May 29, 1880, on page 19, which secures perfect insulation wherever adopted. This method I have since improved by a system of making joints that will admit of instant access for tests and alterations, which vastly increases the practical value of the system.

Before going into further detail on this head, let me endeavour to remove objections that some may regard as standing on the very threshold, and hence demanding first consideration, viz., the questions of right and sightliness involved in proposing to fix the conduits on the fronts of houses along streets. The nearest existing approximation to what is required may be seen on some of the large and handsomely-fitted Atlantic steamers. Walking along the passages between the state rooms everything looks neat and perfectly orthodox in all the details of wood and metal ornament. One of the members, however, of the moulding forming a minor cornice is in reality a tube containing wires, and here and there are ornamental trusses, which being hollow, the removal of two screws allows one to come away and exposes the sockets containing the wire junctions, the wires in which may be instantly tested and the truss as quickly replaced. Equal neatness and sightliness may not be practicable along street frontages, but comparing the effects obtainable by a slight variation of altitude and architectural sham trusses with the present obtrusive ugliness of imitation clothes lines decorated with old paper kites, dead leaves, &c., the choice would be greatly in favour of the new scheme.

As regards the question of compulsory powers by Act of Parliament, which would be required before the owners would allow a 2in. tube to be fixed across their house fronts, it would not be less reasonable than several other restrictions where consent is equally compulsory by existing Acts of Parliament; and if it were a mere choice between crossing one's front by a simple tube or stopping trade by impeding traffic to put wires underground, as well as for frequent repairs, the former would be accepted as the lesser evil.

At the same time I believe it can be made clear that no legitimate interests of private owners would be injured or ignored.

If equal public advantages can be secured by some other plan it is desirable in the interests of all concerned that it should now be made known, but, if not, the few private owners who will be practically or theoretically affected will see that the proposals I shall make for a scale of compensation for right of fixture when taken in connection with a preferential option of being connected to the system at a great reduction of subscription will leave no room for the creation of any grievance.

(*To be continued.*)

NOTES ON ALTERNATE CURRENTS.

BY J. A. FLEMING, M.A., D.SC.

(*Continued from page 286.*)

We proceed to examine the principles underlying the simplest case of alternate or periodic current flow in a linear conductor. Let there be any conductor, such as a wire, of which the cross section is very small, and let this be formed into a coil of many turns and subjected to a simple periodic electromotive force, called hereafter the *impressed electromotive force*, the periodicity being not greater than about 200-300 per second. It is required to find the current at any instant in the wire. The minds of many electrical students, who have been educated too much or too exclusively by contact with continuous currents, are apt to imagine that the simple and familiar law of Ohm is all that is required to meet this case. The supposition is, however, wrong, and the deduction would be found to be disappointed in practice. Every circuit possesses two qualities, which determines the current when it is subjected to a simple periodic electromotive force of given periodicity. These are its *inductance* and its *resistance*. The resistance of a conductor is a quality in virtue of which the passage of a current through it is accompanied by the dissipation of energy—that is, by the irreversible transformation of electric-energy into heat. The inductance of a circuit is a quality in virtue of which the passage of an electric current through it is accompanied by the storage of energy in the form of a magnetic-field. Of the expended energy spent on a conductor (assuming no performance of chemical or external mechanical work) part fritters away into heat by an irreversible process, and part is associated with the circuit in a recoverable form, and is taken up in the establishment of the energy of the magnetic-field, which starts into existence round the conductor. This potential energy, however, dissipates itself as soon as the impressed electromotive force is withdrawn. A mechanical analogy to the operation of starting a current in a wire may be found in the operation of starting from rest, or increasing the speed of a heavy fly-wheel which runs in bearings with friction. On applying a twisting force to the axle of the wheel we get up its speed. To maintain the speed force has to be continually applied, and the work so done against friction is frittered away irreversibly into heat in the bearings. The friction is analogous to the electrical resistance; it may be called the frictional resistance.

When the speed of the wheel is constant there is, however, associated with the wheel a certain quantity of energy in a kinetic form measured by $\frac{1}{2} I \omega^2$, where I is the moment of inertia, and ω the angular velocity of the wheel. As soon as the maintaining force is withdrawn this accumulated energy

Digitized by Google

dissipates itself in heat by friction, or is utilised in some other way. During the time that the speed of the wheel is being increased, force must be applied to it for two purposes. First to increase the angular momentum, and secondly to overcome the friction at the bearings. Suppose that instead of revolving on bearings with friction, the fly-wheel revolves in a more or less viscous fluid, and that the bearings are truly frictionless. In such case the frictional resistance to motion would be fluid resistance, and would for low speeds be approximately proportional to the angular velocity. If I is the moment of inertia and ω the angular velocity of the wheel at any instant, then it is shown in treatises on dynamics that $I\frac{d\omega}{dt}$ is at any instant a measure of the couple or twisting force acting on the wheel to increase its angular velocity, friction being neglected. If we call the friction coefficient B, then $B\omega$ is at any instant the measure of the force necessary to maintain the motion against friction, and the total torsional or twisting force acting on the wheel to maintain its angular velocity against the force of friction, and to increase it against the force of inertia, is

$$F = B\omega + I\frac{d\omega}{dt}.$$

A precisely similar equation may be found connecting the electromotive force, current resistance, electrical and inductance in the case of current starting in a wire. The above equation gives us a value for the instantaneous angular velocity, or enables us to find the angular velocity after any time when F, B, and I are given. When a current of strength i is flowing steadily in a linear conductor, such as the wire under consideration, the energy associated with it in the form of a magnetic field is measured by the quantity $\frac{1}{2}Li^2$, where L is the quantity called the inductance of the circuit. Since this quantity L bears to electro-magnetic energy a relation similar to that which the moment of inertia of a wheel does to the energy of its rotation, it might be called the coefficient of electro-magnetic inertia; but as this would be a cumbersome name, it has been called the inductance, or more frequently the self-induction of the circuit. Similarly the product of the moment of inertia and the angular velocity of the wheel is called the angular momentum, and analogously the product of the inductance of a circuit and the current flowing at that instant through it is called the electromagnetic momentum. The rate at which the angular momentum of a wheel is increasing or diminishing at any instant is a measure of the rotational force, or the couple acting on it at that instant. So also the rate of change of the electro-magnetic momentum of a circuit is the measure of the electromotive force acting on it as far as mere change of current strength is concerned, and omitting, for the present, that part of the electromotive force required to overcome the Ohmic resistance. We have, then, the following parallel between a fly-wheel, with moment of inertia I, revolving frictionlessly and having an angular velocity ω at any instant, and an electric circuit of inductance L, having a current of strength i flowing in it at any instant:—

Angular kinetic energy of the wheel, or energy of rotation	=	$\frac{1}{2}I\omega^2$
Electro-magnetic energy of the circuit	=	$\frac{1}{2}Li^2$
Angular momentum of wheel	=	$I\omega$
Electro-magnetic momentum of the circuit	=	Li
Rate of change of angular momentum of wheel = couple or torsional force causing rotation......	=	$I\frac{d\omega}{dt}$
Rate of change of electro-magnetic momentum = electromotive force employed in changing current strength	=	$L\frac{di}{dt}$

In the electric circuit, over and above the electromotive force which is, so to speak, used up in changing electro-magnetic momentum, there is an amount required to overcome the frictional resistance of the wire, and which, as it is defined and measured by Ohm's law $E = Ri$, may be called the Ohmic resistance. Hence, at any instance if E is the impressed electromotive force acting on the circuit and causing a current i, we may divide E into two parts, one part equal to Ri by Ohm's law, which is sometimes called the effective electromotive force, and another part $L\frac{di}{dt}$, which is the part operating to change the strength of the current, at that instant, producing a small change, di, in the current strength i in a time dt.

Hence
$$E = Ri + L\frac{di}{dt}.$$

This is the fundamental equation for varying or periodic currents, when the periodicity is not so rapid as to affect the uniform distribution of the current over the cross section of the wire, and when the electrostatic capacity may be neglected. The part $L\frac{di}{dt}$ is often called the counter-electromotive force of self-induction, and the above equation might be read in words—

$$\text{Impressed E.M.F.} = \text{Effective E.M.F.} + \text{Counter E.M.F. of self-induction.}$$

We might otherwise arrive at this fundamental equation thus: The total rate of expenditure of energy in a circuit is at any instant measured by the product of the current at that instant existing in the wire and the difference of potential between its ends. The energy expended in the circuit is at any instant being partly dissipated at a rate equal to Ri^2, R being Ohmic resistance, and i current, and partly being stored up in the field at a *rate* equal to $\frac{d}{dt}\left(\frac{1}{2}Li^2\right)$. Hence we have:—

$$\text{Rate of supply of energy} = \text{Rate of dissipation of energy as heat} + \text{Rate of absorption or storage of energy as magnetic field.}$$

and this in symbols is—

$$Ei = Ri^2 + \frac{d}{dt}\left(\frac{1}{2}Li^2\right)$$

or

$$E = Ri + L\frac{di}{dt},$$

which is our fundamental equation.

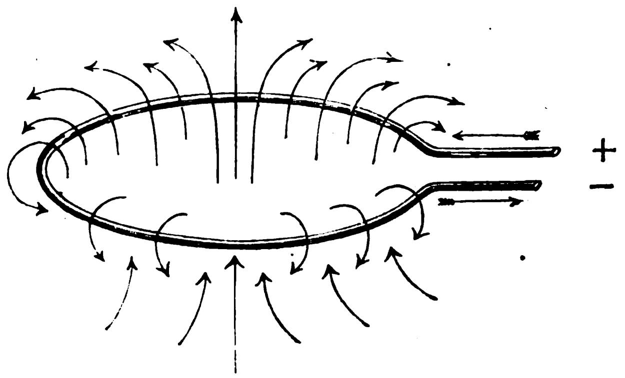

Fig. 18.

We may interpret this equation by looking at it from the point of view of Faraday rather than Clerk Maxwell. When a current is flowing in a conductor, we may picture it as surrounded by its lines of electro-magnetic force *properly* mapped out. That is so that the number of the lines of force passing perpendicularly through a unit of area taken at any point in field is equal to the numerical value of the mean strength of magnetic field over that area. If the circuit has the form of a loop (Fig. 18) lying on a horizontal plane, with the current circulating round it in the opposite direction as the hands of a watch rotate, then the lines of force must be considered as springing out from the upper surface, and turning outwards and over the conductor, so as to re-enter the loop from the under surface. The closed circuit is therefore linked with a certain number of lines of force, which, if the circuit is composed of non-magnetic material, are proportional

Digitized by Google

in number to the strength of the current at that instant. Any increase in strength of the current causes more lines of force to grow out from the circuit, and packs the loop fuller of lines of force. By Faraday's law, any increase of the number of lines of force traversing or linked with a circuit creates an induced electromotive force numerically equal to the rate of increase of that number at that instant. Hence, if 100 million lines of force—C.-G.-S. measure—are put or inserted at a uniform rate in one second into a circuit, it will create an induced E.M F. of one volt in it. But if lines of force are thrust into a circuit the direction of the current induced is counter clock-wise, as seen from that side of the circuit at which they are thrust in (*see* Fig. 19).

Applying this to the case of self-induction, it is easily seen that any increase of current strength in the circuit in Fig. 18 crowds the space with more lines of force, and therefore creates in it an electromotive force of self-induction opposed to the impressed electromotive force which is acting to increase the current, and as long as the current is increasing this counter E.M.F. is at each instant proportional to the rate of growth of the current strength.

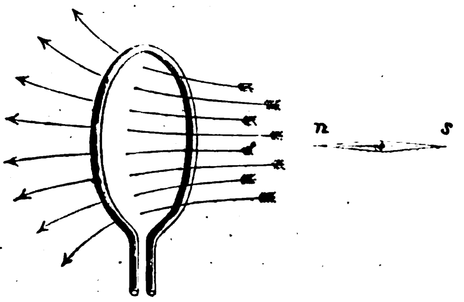

Fig. 19.

Lines of force being crowded into a circuit, inducing a counter clock-wise E.M.F., as seen from the side at which they are put in.

We can cast our current equation—

$$E = R\,i + L\frac{d\,i}{d\,t}$$

into another form, thus :—

$$\frac{E}{R} - i = \frac{L}{R}\frac{d\,i}{d\,t},$$

where $\frac{E}{R}$ is the maximum value which the current can attain, let us call this I; the quantity $\frac{L}{R}$, or the ratio of the inductance to the resistance of the circuit, is called the *time constant* of the circuit; let this quantity be denoted by T. We then have

$$I - i = T\frac{d\,i}{d\,t},$$

which, in words, is a statement that if a steady E.M.F. is made to act on any circuit whose time constant is T, the amount by which at any instant the current falls short of its full value is equal to its rate of growth at that instant, multiplied by the time constant.

(*To be continued.*)

CABLE TESTING.—THE FALSE ZERO METHOD.

BY M. EMILE LACOINE.*

This method is well known to all electricians who have to do with cable testing, but it appears to me that a misapprehension exists in the minds of most of those who have written on the subject. Take as an example the description in the admirable "Pocket-Book of Electrical Books and Tables," by Munro and Jamieson (p. 141, second edition), which is as follows :—

"1. Join up as in figure, and obtain 'false zero,' *i.e.*, the deflection on galvanometer G, due to cable or earth currents [call this deflection D]. This is done by inserting a resistance, R, *equal to the battery resistance* between centre of bridge at 3 and earth (Fig. 1); the battery B being out of circuit, the earth-current flows on, depressing K_2 partly through galvanometer to earth [and in part it traverses the resistance *d*, which is already approximately adjusted to *c*].

"2. Cut R out of circuit, and apply + or − pole of battery B, by key K_1, adjusting the resistance *d* to the 'false zero' [so as to reproduce the deflection D].

We have then $c = d \cdot \frac{a}{b}$ for the resistance sought."

The usefulness of the method is, however, much impaired by the supposed necessity for knowing the resistance of the battery, which involves a preliminary test; but is it really necessary to make the resistance R equal to that of the battery? I have made a great use of the method, and in practice, I have never found that this is necessary.

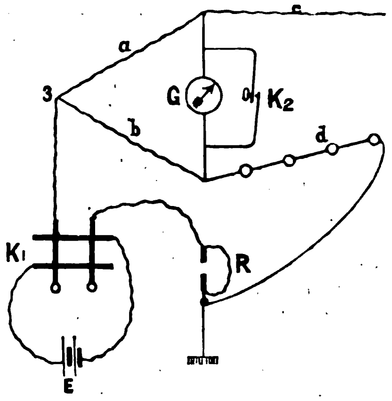

Fig. 1.

Even so high an authority as Mr. Kempe is, however, under the impression that the theory of the test requires this condition, and in his standard work on "Electrical Testing," he gives a proof in which this condition is assumed. I shall therefore show, mathematically, that this resistance may be entirely dispensed with.

This result follows at once as a consequence of the general law of Dr. Frölich (see *Wied. Ann.*, Vol. XXX., No. 1, 1887). It can also easily be proved by the following simple application of Kirchhoff's laws :—

Fig. 2 is a diagram of the first operation in which the battery is out of circuit, and any resistance whatever (*p*′)

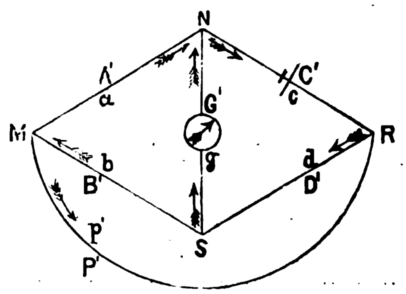

Fig. 2.

occupies its place. [The cell in the branch C represents, of course, the "earth current" in the actual test.] Fig. 3 represents the second operation with the battery of resistance *p* in circuit. The italic letters represent the resistances which, save *p*, are invariable. The capital letters with accents represent the currents in Fig. 2, and those without accents represent the currents in Fig. 3. *a* and *b* are the ratio arms of the bridge, and *d* the adjustable resistance.

We have, according to the law of Kirchhoff (Fig 3),

$$A\,a - G\,g + B\,b = 0,$$

and similarly, in Fig. 2,

$$A'\,a - G'\,g + B'\,b = 0.$$

* From the *Journal Télégraphique*, 25 January, 1888 (p. 12).

Digitized by Google

And as G = G′ we get

$$\mathrm{A}a+\mathrm{B}b=\mathrm{A}'a+\mathrm{B}'b.$$

But we have also

$$\mathrm{B}=\mathrm{A}+\mathrm{P} \quad \text{and} \quad \mathrm{B}'=\mathrm{A}'+\mathrm{P}';$$

whence, replacing B and B′,

$$\mathrm{A}a+\mathrm{A}b+\mathrm{P}b=\mathrm{A}'a+\mathrm{A}'b+\mathrm{P}'b$$

$$\mathrm{A}a-\mathrm{A}'a+\mathrm{A}b-\mathrm{A}'b=\mathrm{P}'b-\mathrm{P}b$$

or

$$(\mathrm{A}-\mathrm{A}')(a+b)=b(\mathrm{P}'-\mathrm{P}). \quad (1).$$

In the circuit N R S, we have similarly

$$\mathrm{C}c+\mathrm{D}d+\mathrm{G}g=e \qquad \mathrm{C}'c+\mathrm{D}'d+\mathrm{G}'g=e;$$

whence, as before,

$$\mathrm{C}c+\mathrm{D}d=\mathrm{C}'c+\mathrm{D}'d.$$

But we have also

$$\mathrm{D}=c+\mathrm{P} \quad \text{and} \quad \mathrm{D}'=c'+\mathrm{P}';$$

whence, replacing D and D′,

$$\mathrm{C}c+\mathrm{C}d+\mathrm{P}d=\mathrm{C}'c+\mathrm{C}'d+\mathrm{P}'d$$

$$\mathrm{C}c-\mathrm{C}'c+\mathrm{C}d-\mathrm{C}'d=\mathrm{P}'d-\mathrm{P}d,$$

or

$$(\mathrm{C}-\mathrm{C}')(c+d)=d(\mathrm{P}'-\mathrm{P}). \quad (2).$$

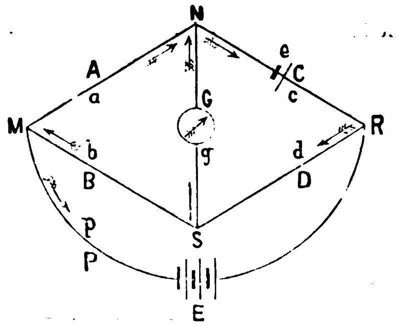

FIG. 3.

Dividing equation (1) by (2) we have

$$\frac{(\mathrm{A}-\mathrm{A}')(a+b)}{(\mathrm{C}-\mathrm{C}')(c+d)}=\frac{b}{d}. \quad (3).$$

But we have again

$$\mathrm{A}+\mathrm{G}=\mathrm{C},$$

$$\mathrm{A}'+\mathrm{G}'=\mathrm{C}'.$$

By subtraction

$$(\mathrm{A}-\mathrm{A}')=(\mathrm{C}-\mathrm{C}').$$

So that equation (3) reduces to

$$\frac{a+b}{c+a}=\frac{b}{d};$$

whence we have, lastly,

$$c=d\cdot\frac{a}{b}.$$

We see then that the value of c is not only independent of the E.M.F. of the battery, but also of its resistance and of the substituted resistance p', which may be anything we please. Therefore, an auxiliary resistance is useless, and we may short-circuit this branch altogether.

We may even open this branch without affecting the conditions; we then return to the well-known method of Mance for measuring the internal resistance of a cell. It will be seen at once that if in formulæ (1) and (2) we make P′ = 0, we arrive at the same values in (3) as before.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper, "The Alexandra Dock, Hull. By Mr. A. C. HURTZIG, M.I.C.E.

SOCIETY OF ARTS.

8 p.m. Foreign and Colonial Section. "British Columbia." By HENRY COPPINGER BEETON, Agent-General for British Columbia.

ROYAL INSTITUTION.

3 p.m. Lecture, "Before and After Darwin" (4). By Mr. G. J. ROMANES, M.A., &c.

ROYAL VICTORIA HALL (Waterloo Bridge-road, S.E.).

Lecture, "Germs in the Air, and What They Do for Us." By Dr. PERCY F. FRANKLAND, B.Sc., F.C.S. Chairman, Sir GEO. YOUNG.

WEDNESDAY, February 8th.

SOCIETY OF ARTS.

8 p.m. Ninth Ordinary Meeting. "The Continuation of Elementary Education." By Mr. W. LANT CARPENTER, B.A. The Right Hon. Sir LYON PLAYFAIR, K.C.B., M.P., F.R.S., will preside.

THURSDAY, February 9th.

ROYAL INSTITUTION.

3 p.m. Lecture, "Early Secular Choral Music" (1). By Prof. C. H. H. PARRY.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

8 p.m. Ordinary Meeting. "Alternate Current Transformers, with special reference to the best Proportion between Iron and Copper." By Mr. GISBERT KAPP., A.M.I.C.E., Member.

ROYAL SOCIETY.

4.30 p.m. Ordinary Meeting.

SOCIETY OF ARTS.

8 p.m. Special Lecture, "Etching and Mezzotint Engraving." By Prof. HUBERT HERKOMER, A.R.A.

FRIDAY, February 10th.

ROYAL INSTITUTION.

9 p.m. Discourse on "Safety Lamps in Collieries." By Mr. W. H. PREECE, F.R.S., M.R.I.

INSTITUTION OF CIVIL ENGINEERS.

7.30 p.m. Supplemental Meeting for Students. Paper, "Arched Ribs and Voussoir Arches." By Mr. H. MEDWAY MARTIN, Wh. Sc., Stud. Inst. C.E.

PHYSICAL SOCIETY OF GLASGOW UNIVERSITY.

"Apparatus for Determining the Horizontal Component of the Earth's Magnetism." By Mr. T. GRAY, B.Sc., &c.

SOCIETY OF ARTS.

8 p.m. Indian Section. "The Work of the Afghan Frontier Commission." By Captain MANIFOLD, R.A. Mr. J. M. MACLEAN, M.P., will preside.

SATURDAY, February 11th.

ROYAL INSTITUTION.

3 p.m. Lecture, "Experimental Optics" (4). By Lord RAYLEIGH.

The Electrician.

ublished every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial and Publishing Offices
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714.

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* THE PROPRIETORS.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at Messrs. Smith and Sons' railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained at all Booksellers and Newsvendors; or direct from the office as above.*

The rates of subscription to "THE ELECTRICIAN" *(including postage) are as follows:—*

	3 months. s. d.	6 months. s. d.	12 months. s. d.
For the United Kingdom	4 11	9 9	19 6
,, Foreign Parts and Colonies:— Within Postal Union	6 6	11 0	22 0
,, Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	6 1	12 1	24 2

"The Electrician" in America.

"THE ELECTRICIAN" *can be obtained in America from* D. VAN NOSTRAND, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not ater than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

THE ELECTRICIANS' DIRECTORY.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY IS NOW READY.

NOW READY.

Volume XIX. of "The Electrician," strongly bound in cloth, is NOW READY, price Ten Shillings and Sixpence.

Cases for binding "The Electrician," price Two Shillings, Now Ready.

ANSWERS TO CORRESPONDENTS.

R. BISHOP (Colchester).—*We regret that we cannot undertake to inform you which is the best engine, or dynamo, or battery, nor which is the best firm to whom to apply. Any respectable firm of electrical engineers would, however, be perfectly well able to satisfy your requirements.*

J. W. C.—*The following are some of the public institutions in the metropolis which are now provided with electric light; the list is short and perhaps incomplete:—The Houses of Parliament (in part), The British Museum, South Kensington Museum, The New Law Courts, Bethnal Green Museum, The General Post Office (in part).*

THE POSTMASTER-GENERAL AND THE TELEPHONES.

Although the speech made by the POSTMASTER-GENERAL in reply to a deputation from the Wolverhampton Chamber of Commerce last Friday was in every way unsensational and even commonplace, that portion of it which related to telephonic business has evidently created a good deal of excitement among dealers in telephone shares. According to one financial authority, Mr. RAIKES' words, if they had been first dropped in Capel-court, would have been worth to him a cheque for a good round sum. The plain meaning of this mysterious remark is that the declaration he was about to make would certainly send up the price of telephone property, and that his evident indifference to the consequences which have actually followed provokes some surprise in financial circles. Probably the consequences were inevitable, no matter how long the announcement might have been delayed, and perhaps the POSTMASTER-GENERAL had excellent reasons for thinking that the sooner it was made, and the disturbance occasioned by it abated, the better it would be for the shareholders. They are now in possession of a pretty distinct declaration of policy on the part of the Post Office, and have ample time to regulate their conduct accordingly. But there is nothing remarkable in the declaration itself. It might have been foreseen many years ago, and has certainly been growing imminent year by year. But to infer from what has now transpired that the telephone companies will gain by the Post Office acting on the line of policy thus indicated more than by carrying on their own business as heretofore seems to us somewhat rash. The words of the POSTMASTER-GENERAL do not warrant such an inference, the circumstances of the case do not justify it, and the recent negotiations between the Post

Digitized by Google

Office and the submarine cable companies do not at all encourage it.

If he has been correctly reported, Mr. RAIKES simply deprecated the competition of private companies with the Post Office for telephone business, and predicted that before long telephony in this country must be placed on the same footing as telegraphy. Readers of these pages will be quite familiar with the view here enunciated; but with a slight verbal difference. As a matter of fact, there is no competition between the parties. What Mr. RAIKES, therefore, seems to object to is the absorption by private companies of business which he regards as rightly belonging to the Post Office. Mr. RAIKES is not responsible for the state of affairs, which has grown out of the compromise following on the great lawsuit between the Post Office and the original company; and he is free to state in effect that the arrangement was from the very first unlikely to assume a permanent character. On the part of the Post Office there is virtually no competition at all; and, except in one or two isolated places, the department has had no opportunity of showing the public what the telephone is capable of if taken in hand solely in the public interest and not as a commercial speculation. Obviously the State can never risk public money by competition in the ordinary business sense of the term; and in this particular case the Post Office was utterly disabled from doing so by the fact that it accepted a royalty on the business of all its possible competitors. To take the royalty and try to acquire the earnings would have been in the highest degree unfair; and the result has been that the companies have had a free hand, hampered only by the condition that, for depriving the Post Office of what the law had declared to be its legitimate business, a portion of their receipts should be handed over to the public revenue. Naturally, the original concession and its obligation have come to be quite forgotten, and for some time past the royalty paid to the Post Office has been denounced as a tax on telephonic enterprise; and the public usually take the view that the Government does its utmost to check the growth of telephonic business by increasing its necessary charges because of the royalty.

Now, if there is much ground for this contention—and undoubtedly there is some—it furnishes a most excellent reason for putting an end to the bargain. To a certain extent the customers have to pay for a double profit, the profit earned by the company and the unearned profit legally accruing to the Post Office. This is not only wasteful but exasperating, and when it is added that for every shortcoming of the service excuses are pleaded which directly or indirectly fix the blame on the Government, and tend to lower the standard of telephonic efficiency all round, it is plain that a state of things has been reached which amply explains the dissatisfaction with which it is viewed by the POSTMASTER-GENERAL. Nor is this all; representing a public department directly responsible for the telegraphs of the country and morally responsible also for its telephones—a responsibility incurred by the acceptance of telephone royalties, he naturally looks with disfavour on the growth of a vast monopoly associated with, but independent of, his department—a monopoly over which he has absolutely no control, but for the conduct of which he is constantly called to account. Our readers will acquit us of using the term monopoly in any offensive sense, and we have certainly no specific objections to urge against the monopoly freely conceded to, and fairly worked by, the parent telephone company. But its exclusive rights have confessedly not led to a very rapid popularisation of the telephonic system as a means of social and commercial intercourse. And this fact must be especially galling to the head of the Post Office, who is as much crippled in the matter as the meanest of Her Majesty's subjects. It may not be generally known, but the Post Office have reserved no rights in the telephone for themselves, and are sharply watched—so we are credibly informed—in every petty detail of the instrument, besides being forced to pay the market price for what the department could manufacture quite as well for itself and much cheaper. Interpreted into plainer language, what the POSTMASTER-GENERAL means is, we suspect, that, not the competition, but the monopoly of these private companies is "unsatisfactory."

If the position of the Post Office, unable to serve the public in its own way and powerless to influence the companies in any way whatever, has thus become almost intolerable, that of the companies is hardly less so. Their future is extremely uncertain, both in respect to the patents on which their existence largely depends, and the strained relations which are said to have long subsisted between the owners and the Government. Not only this, their system of overhead wires in populous towns is growing more and more objectionable with the extension of business, and a vast outlay on some scheme of reorganisation may soon be imperative. Moreover, the prospects of legislation favourable to an extension of their rights in this direction are, we believe, farther off than ever. It would rather surprise us if, as a contemporary ventures to predict, a "Postal Telephone Bill" were introduced in the coming Session; but under present circumstances the passing of the Bill for enlarging the powers of the telephone companies would surprise us still more. It is not the fact, as asserted by the same journal, that our telephone system is inferior to that of every country in the world. On the contrary, it is in all respects superior to that of every country in Europe; and in point of cheapness is not inferior to the American system. But somehow or other the English telephone companies have not made friends in or out of Parliament. They have always seemed to be working on for very life, making sure of their footing in order to establish a permanent right to existence; and this with often too little regard for public sentiment, safety, or convenience. This is not the time to blame them for what they have done or neglected to do. Their tenure has been precarious and anomalous from the very first, the chief persons in fault being those advisers of the then Government who, after fighting a legal battle, were at the same time too timid to seize the spoils of victory, and not magnanimous enough to abandon the indemnity. It has all along been evident that this "unsatisfactory" arrangement must one day come to an end. But we do not attach much immediate significance to the POSTMASTER-GENERAL'S words; and we by no means share the sanguine expectations which seem to be indicated by a general rise in telephone shares. Until something is heard about the terms on which telephones are to be "placed on the same footing as telegraphs" there will be nothing to warrant any unnatural fluctuation in the price of telephone shares.

DYNAMOS WITH INTERNAL POLES.

In our recent review of the progress of electrical engineering during the past year we referred to the fact that in Germany no less than four manufacturers have taken to the construction of dynamos with internal poles. Messrs. Siemens and Halske, Messrs. Ganz and Co., the Helios Company, and Mr. Fein are now producing machines of this type. The machine which we illustrate herewith is built by the latter maker. It does not at first sight seem very clear that the advantages obtained are sufficient to counterbalance the ob-

Digitized by Google

jections to an overhung armature and the mechanical difficulties of winding the coils.

The machine illustrated in Fig. 1 is intended for an output of 15,000 watts when driven at 520 revolutions per minute, and its total weight is only 14½cwt. The weight of copper on the armature is 39lb.; that on the four magnet cores, which are arranged as shown in the sketch, Fig. 2, is 158lb. The resistance of the armature is ·052 ohm. The machine is compound wound, and the resistance of the main circuit—that is, of the four main exciting coils coupled in parallel, is ·023 ohm; that of the shunt circuit, 28 ohms. The current is 136 amperes, and the terminal pressure 110 volts. The inner diameter of the armature when wound is 19⅝in., the external diameter is 25in., and the length 6½in. The core consists of two hundred soft iron discs, insulated with paper, and mounted on and supported by twelve insulated bolts. This core is wound with one layer of square wire in 576 turns, connected Gramme fashion with a large commutator containing ninety-six parts. The field-

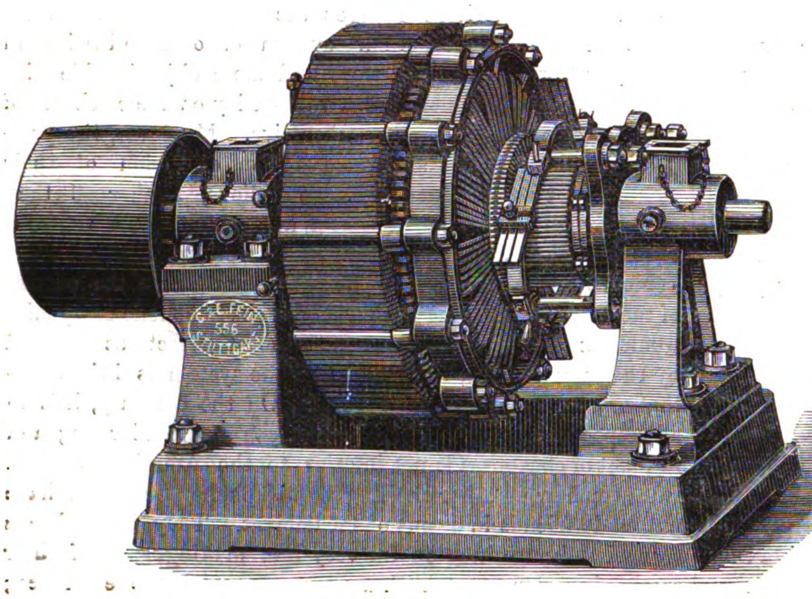

Fig. 1.

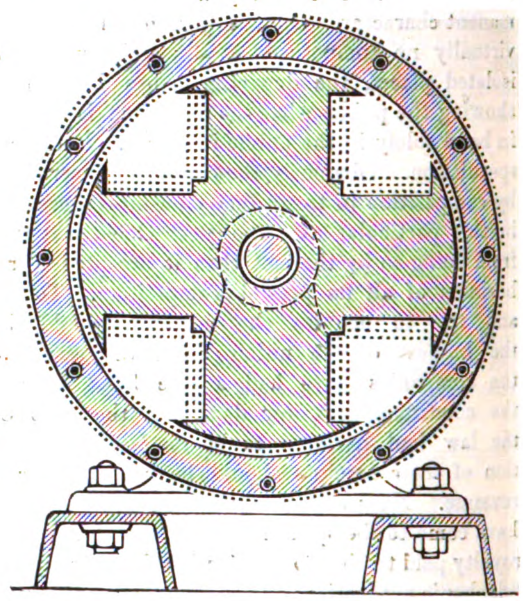

Fig. 2.

magnet cores are square, with rounded corners, each being wound with seventy-two turns of main wire and eleven hundred turns of shunt wire. From these figures it follows that at full output the main exciting power is 4,900 ampere-turns, and the shunt exciting power 8,900 ampere-turns, or a total of 13,800 ampere-turns.

We also illustrate in Fig. 3 an American machine with internal poles. This is the Clarke dynamo, which has made some stir in America, though perhaps some of our readers will

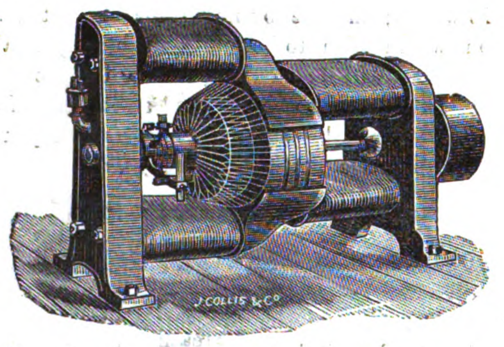

Fig. 3.

be inclined to think it rather an example of "how not to do it."

It would be interesting to know in this case what method has been adopted for holding the armature wire, there being no information at present on this point.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

Chapter VII.—*Simple Tests with Indicators (continued).*

(*Continued from page 289.*)

75. *(b) Tests for Identity of Wires.*—The detector is a ready means of identifying wires which are run together from, say, one part of a building to another, no distinguishing mark having been attached to them, or which have become mixed in passing together through walls or flooring. Gutta percha covered wires for telegraph work are manufactured with one or more ridges of insulating material running along their entire length, in which case any particular wire can be identified at any point by feeling its surface. Wires insulated with this distinguishing mark are in use at some cable stations, and serve to connect the cables from the beach at low-water mark to the cable house or thence to the town office. They are drawn through iron pipes laid underground, the latter being kept filled with water to preserve the insulation. In this case any wire can easily be identified by the number of ridges on its exterior.

For electric bell work the outside cotton coverings of wires leading from the different rooms to the annunciator are some-

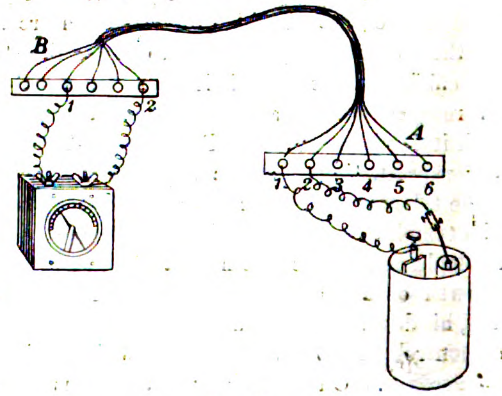

Fig. 35.

times differently coloured, so that anywhere throughout their length they can be identified.

Suppose, now, that it is required to identify six wires laid from a battery room to an office. We should start by numbering the wires at one end A (Fig. 35), and then connect, say,

Digitized by Google

the copper pole of a cell to No. 1, and the zinc pole to No. 2. Now, on going to the other end B and trying the wires successively on the detector, the pair of wires that cause a deflection are, of course, Nos. 1 and 2; but this alone does not show which is which. This is determined by the *direction* of the deflection. Suppose that by a previous trial it had been ascertained that when a cell was connected up directly to the detector the needle was deflected *towards* the terminal at which the current *entered* the instrument (*see* Chap VI., para. 56) we should know that the needle would point towards the terminal connected to No. 1. We have therefore identified Nos. 1 and 2, and they should be so marked at once. No. 1 may now be kept attached to one pole of the cell in the battery room, and one terminal of the detector in the office, while all the other wires are identified in turn. Thus, No. 3 being connected to the other pole of the cell, the wire which when touched by the other terminal of the detector gives a deflection is No. 3, and so on, till the last but one is done, and then all are known.

76. (*c*) ***Test for Insulation.***—A sensitive indicator of the horizontal type described in para. 72 and illustrated in

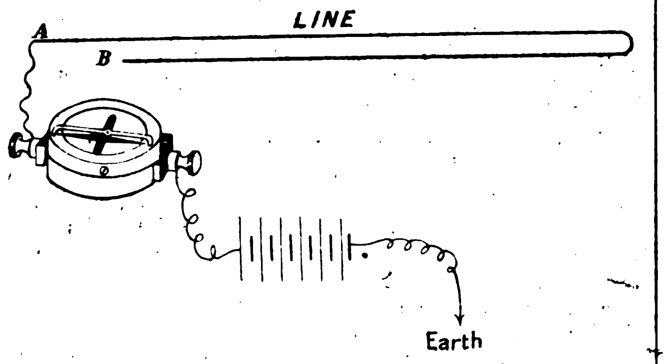

FIG. 36.

Fig. 31 may be used for testing the insulation of a circuit where it is not so important to know the exact resistance of the insulation when perfect as to keep up a daily inspection that it does not fall below a certain amount. An indicator of

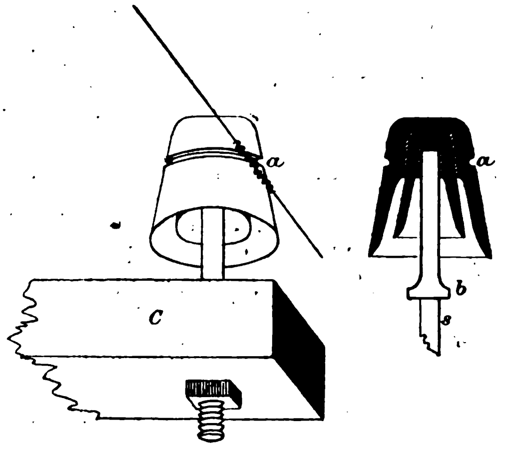

FIG. 37.

this type will give 10deg. deflection with one Leclanché cell and 150,000 ohms in the *external* circuit, the coil of the instrument itself measuring 1,000 ohms. With these high resistances, that of the cell would be practically negligible. Up to such a small angle as 10deg. the deflections may be taken as proportional to the currents, and therefore inversely proportional to the total resistances of the circuit. That is, 1deg. deflection would represent (150,000 + 1,000) 10 = 1,510,000 ohms, or 1·51 megohms total resistance, which, deducting the resistance of the instrument, would be 1·509 megohms in the external circuit.

By increasing the number of cells the instrument could be made to read up to a much higher resistance.

The connections would be made as in Fig. 36, the battery being connected through the instrument to one end of the main wire, whose insulation resistance is to be found, the other end, B, of the wire not touching anything, or as it is termed left "free." The other pole of the battery must be connected to earth, this connection being easily made on to a water pipe which runs underground. If this connection is made permanently it must not be to a *lead* gas pipe, or indeed to any *lead* pipe, a plate of galvanised iron sunk in the ground being the best. Now, let us suppose that the wire A B is an aerial one, and is run on poles either from roof to roof, as is the case in London with the electric lighting and telephone wires, or on poles along the streets, as with arc lighting, telephone, and telegraph wires in the provinces. At every post the line wire is bound by wire to a porcelain insulator at the groove marked *a* in Figs. 37 and 38, which ex-

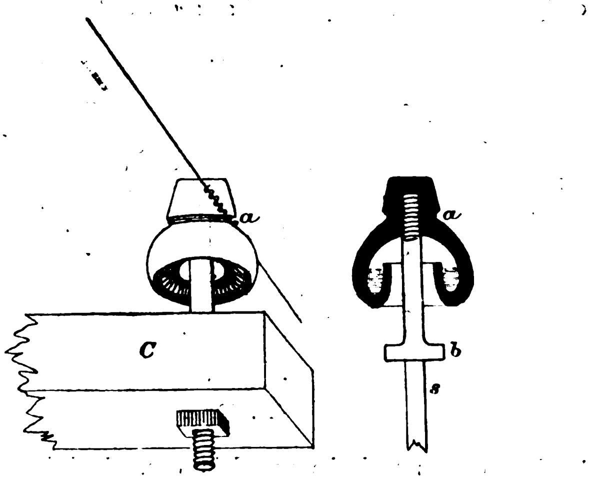

FIG. 38.

hibit two most approved forms largely in use now. Mr. Latimer Clark's double-cup form, shown in Fig. 37, presents a large insulating surface between the wire at *a* and the iron stalk S, for any leakage of current from the wire down the post to earth must occur over the two outer and two inner

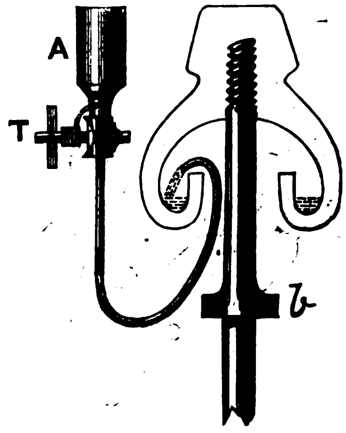

FIG. 39

surfaces of the cups before the stalk is reached. Messrs. Johnson and Phillips's fluid insulator is shown in Fig. 38, in section, and as attached to the cross arm, C, of a post. It will be seen that the lip of the insulator is turned up at the lower end, forming a well which is nearly filled with insulating oil, any leakage of current, therefore, having to traverse the outside and inside surfaces of the porcelain cup and over the surface of the fluid. The well of this insulator is filled with a measured quantity of oil by the siphon shown in Fig. 39, which is manipulated by first filling the siphon tube with oil, then closing the tap T and filling the reservoir A. This reservoir then contains exactly

Digitized by Google

the proper quantity of oil, which is delivered into the well of the insulator when held as shown in the figure, and the tap T opened. The siphon tube does not, of course, require refilling, and the next is proceeded with by closing T and filling A as before. This form of insulator offers a high insulation resistance to leakage, and is specially suitable for electric lighting circuits where the high E.M.F. in use tends to open up the weak points in the insulation. These insulators are fixed up by passing the stalk through a hole bored in the cross-arm C of the post, as far as the projection *b*, the nuts then being screwed on underneath, fixing them firmly in position. To avoid the strain on the insulator when the wire to and from it forms an angle, and to overcome the friction between insulator and wire when the latter is heavy or the span between two posts is long, the *shackle* insulator is employed. A double shackle insulator, supporting an electric light insulated main wire, and bolted to an iron pole, is shown in Fig. 40. The wire itself is always continuous at the shackle, and in the case of lighting wires is firmly bound at *a a* with tarred twine after

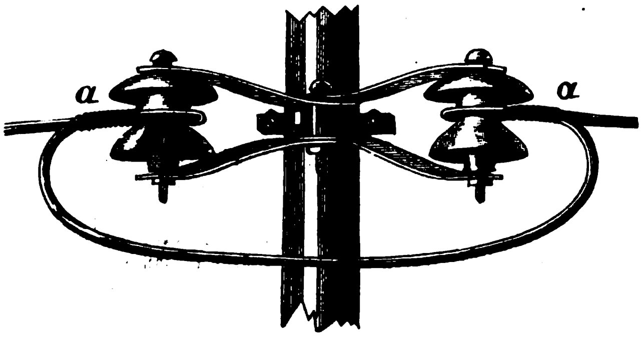

FIG. 40.

bending once round the porcelain cup. Lighting wires in London are run in this way, shackles being fixed to every pole to bear the strain of the heavy wire, and the iron poles themselves being planted on roofs of buildings, and kept in their position by wire rope stays. In addition to shackling, the strain of heavy wires is borne by a

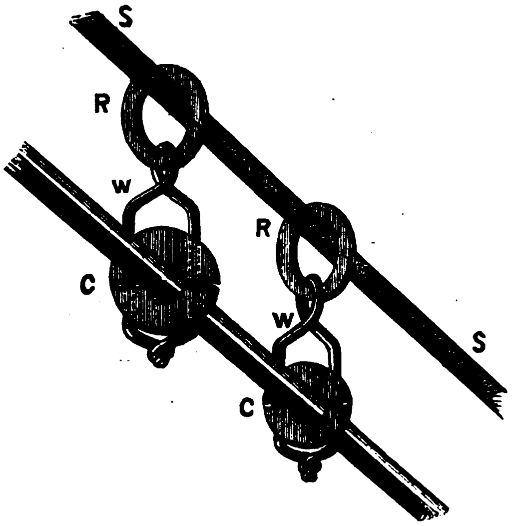

FIG. 41.

steel wire rope suspender, S S (Fig. 41), which illustrates one method of attachment. A vulcanite chair, C, carries the electric light wire, and this is suspended from the stranded steel wire by means of a galvanised iron wire loop, W, passed through the vulcanite chair, engaging in a split steel ring, R, which is threaded on the steel wire. The "shackling off" of a telegraph or telephone wire is somewhat different. About 2ft. of line wire is bound to each porcelain cup first, the line wire is then soldered to one of these ends, and brought round to the other end and soldered and carried on, slack being left between the two joints.

The insulation resistance of each porcelain insulator is tested under rigorous conditions after manufacture, being allowed to soak in water for forty-eight hours previous to testing, the resistance then averaging from 500,000 to four million megohms each (Prof. Ayrton in "Practical Electricity"), or say, on an average, one million megohms per insulator. When put up on a line and subjected to rain and dust the insulation resistance is, of course, reduced. In fine dry weather an insulation resistance up to 14 megohms per mile is obtained, but in wet weather it may fall to about $\frac{1}{50}$th of this; in any case it should not fall below 200,000 ohms per mile of line for telegraph and telephone work. In electric lighting by arc lamps in series with *direct* currents, or by incandescent lamps with *alternating* currents, and *transformers* in series, if the wires are run overhead in the above manner the insulation falls to a lower figure when *working*, owing to the high E.M.F. worked with, which tends to open up weak places in the insulating supports. For all lighting circuits, however, the wire is itself insulated and then wrapped round with a serving of tape. An arc light circuit will offer from one to two hundred thousand ohms insulation resistance per mile. Taking a line offering 200,000 ohms per mile, each resistance to leakage of 200,000 ohms is in *multiple arc* or *parallel circuit* with the others. Two miles would therefore measure 100,000 ohms, ten miles 20,000, and so on, and, the resistance being uniform, the rule is, divide the resistance per mile by the number of miles to obtain the total insulation resistance of the line.

It will be seen, therefore, that if even such a short length as one mile of overhead wire is taken, an insulation test with a delicate horizontal indicator as described above, would readily show whether the insulation was up to or below its required value; but with a longer line, the insulation resistance being reduced, the instrument would more sensitively detect changes. The writer has seen satisfactory tests taken this way with a similar instrument on an arc lighting circuit, the more delicate instruments not being always available or practicable to use.

(To be continued.)

ELECTRO-CHEMICAL THERMO-DYNAMICS.

(Letter from Prof. Willard Gibbs to the Secretary of the Electrolysis Committee of the British Association.)

Newhaven, Nov. 21st, 1887.

Professor Oliver J. Lodge.

Dear Sir: As the letter which I wrote you some time since concerning the *rendement* of a perfect or reversible galvanic cell seems to have occasioned some discussion, I should like to express my views a little more fully.

It is easy to put the matter in the canonical form of a Carnot's cycle. Let a unit of electricity pass through the cell producing certain changes. We may suppose the cell brought back to its original condition by some reversible chemical process involving a certain expenditure (positive or negative) of work and heat, but involving no electrical current nor any permanent changes in other bodies except the supply of this work and heat.

Now the first law of thermo-dynamics requires that the algebraic sum of all the work and heat (measured in "equivalent" units) supplied by external bodies during the passage of the electricity through the cell, and the subsequent processes by which the cell is restored to its original condition, shall be zero.

And the second law requires that the algebraic sum of all the heat received from external bodies, divided each portion thereof by the absolute temperature at which it is received, shall be zero.

Let us write W for the work and Q for the heat supplied by external bodies during the passage of the electricity, and [W], [Q] for the work and heat supplied in the subsequent processes.

Then $$W + Q + [W] + [Q] = 0, \quad (1)$$

Digitized by Google

and $$\frac{Q}{t'} + \int \frac{d[Q]}{t} = 0, \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where t under the integral sign denotes the temperature at which the element of heat $d[Q]$ is supplied, and t' the temperature of the cell, which we may suppose constant.

Now the work W includes that required to carry a unit of electricity from the cathode having the potential V″ to the anode having the potential V′. (These potentials are to be measured in masses of the same kind of metal attached to the electrodes.) When there is any change of volume, a part of the work will be done by the atmosphere or other body enclosing the cell. Let this part be denoted by $W\rho$. In some cases it may be necessary to add a term relating to gravity, but as such considerations are somewhat foreign to the essential nature of the problem which we are considering, we may set such cases aside. We have then

$$W = V' - V'' + W\rho \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Combining these equations we obtain

$$V'' - V' = W\rho + [W] + [Q] - t'\int \frac{d[Q]}{t} \quad . \quad . \quad (4)$$

It will be observed that this equation gives the electromotive force in terms of quantities which may be determined *without setting up the cell.*

Now $[W] + [Q]$ represents the increase of the intrinsic energy of the substances in the cell during the processes to which the brackets relate, and $\int \frac{d[Q]}{t}$ represents their increase of entropy during the same processes. The same expressions, therefore, with the contrary signs, will represent the increase of energy and entropy in the cell during the passage of the current. We may therefore write

$$V'' - V' = -\Delta\epsilon + t'\Delta\eta + W\rho \quad . \quad . \quad . \quad (5)$$

where $\Delta\epsilon$ and $\Delta\eta$ denote respectively the increase of energy and entropy in the cell during the passage of a unit of electricity. This equation is identical in meaning, and nearly so in form, with equation (694) of the paper cited in my former letter, except that the latter contains the term relating to gravity. See *Trans.* Connect. Acad. III. (1878), p. 509. The matter is thus reduced to a question of energy and entropy. Thus, if we knew the energy and entropy of oxygen and hydrogen at the temperature and pressure at which they are disengaged in an electrolytic cell, and also the energy and entropy of the acidulated water from which they are set free (the latter, in strictness, as functions of the degree of concentration of the acid), we could at once determine the electromotive force for a reversible cell. This would be a limit below which the electromotive force required in an actual cell could not fall, and above which the electromotive force of any such cell used to produce a current (as in a Grove's gas battery) could not reach.

Returning to equation (4), we may observe that if t under the integral sign has a constant value, say t'', the equation will reduce to

$$V'' - V' = \frac{t'' - t'}{t''}[Q] + [W] + W\rho \quad . \quad . \quad . \quad (6)$$

Such would be the case, if we should suppose that at the temperature t'' the chemical processes take place reversibly with evolution or absorption of heat, and that the heat required to bring the substances from the temperature of the cell to the temperature t'', and that obtained in bringing them back again to the temperature of the cell, may be neglected as counterbalancing each other. This is the point of view of my former letter. I do not know that it is necessary to discuss the question whether any such case has a real existence. It appears to me that in supposing such a case, we do not exceed the liberty usually allowed in theoretical discussions. But if this should appear doubtful, I would observe that the equation (6) must hold in all cases if we give a slightly different definition to t'', viz., if t'' be defined as a temperature determined so that

$$\frac{[Q]}{t''} = \int \frac{d[Q]}{t} \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

The temperature t'', thus defined, will have an important physical meaning. For by means of perfect thermo-dynamic engines we may change a supply of heat [Q] at the constant temperature t'' into a supply distributed among the various temperatures represented by t in the manner implied in the integral, or *vice versâ.* We may therefore, while vastly complicating the experimental operations involved, obtain a theoretical result which may be very simply stated and discussed. For we now see that after the passage of the current we may (theoretically) by reversible processes bring back the cell to its original state simply by the expenditure of the heat [Q] supplied at the temperature t'', with perhaps a certain amount of work represented by [W], and that the electromotive force of the cell is determined by these quantities in the manner indicated by equation (6), which may sometimes be further simplified by the vanishing of [W] and $W\rho$.

If the current causes a separation of radicles, which are afterwards united with evolution of heat, [Q] being in this case negative, t'' represents the highest temperature at which this heat can be obtained. I do not mean the highest at which any part of the heat can be obtained—that would be quite indefinite—but the highest at which the whole can be obtained. I should add that if the effect of the union of the radicles is obtained partly in work—[W], and partly in heat —[Q], we may vary the proportion of work and heat; and t'' will then vary directly as [Q]. But if the effect is obtained entirely in heat, t'' will have a perfectly definite value.

It is easy to show that these results are in complete accordance with Helmholtz's differential equation. We have only to differentiate the value which we have found for the electromotive force. For this purpose equation (5) is most suitable. It will be convenient to write E for the electromotive force V′ − V″, and for the differences $\Delta\epsilon$, $\Delta\eta$ to write the fuller forms $\epsilon'' - \epsilon'$, $\eta'' - \eta'$, where the single and double accents distinguish the values before and after the passage of the current. We may also set $p\,(v' - v'')$ for $W\rho$, where p is the pressure (supposed uniform) to which the cell is subjected, and $v'' - v'$ is the increase of volume due to the passage of the current. If we also omit the accent on the t, which is no longer required, the equation will read

$$E = \epsilon'' - \epsilon' - t\,(\eta'' - \eta') + p\,(v'' - v') \quad . \quad . \quad . \quad (8)$$

If we suppose the temperature to vary, the pressure remaining constant, we have

$$dE = d\epsilon'' - d\epsilon' - t\,d\eta'' + t\,d\eta' - (\eta'' - \eta')\,dt + p\,dv'' - p\,dv' \quad (9)$$

Now, the increase of energy $d\epsilon'$ is equal to the heat required to increase the temperature of the cell by dt diminished by the work done by the cell in expanding. Since $d\eta'$ is the heat imparted divided by the temperature, the heat imparted is $t\,d\eta'$, and the work is obviously $p\,dv'$. Hence

$$d\epsilon' = t\,d\eta' - p\,dv',$$

and in like manner

$$d\epsilon'' = t\,d\eta'' - p\,dv''.$$

If we substitute these values, the equation becomes

$$dE = (\eta' - \eta'')\,dt \quad . \quad . \quad . \quad . \quad . \quad (10)$$

We have already seen that $\eta'' - \eta'$ represents the integral $\int \frac{d[Q]}{t}$ of equations (2) and (4), which by equation (2) is equal to the reversible heat evolved, − Q, divided by the temperature of the cell, which we now call t. Substitution of this value gives

$$\frac{dE}{dt} = \frac{Q}{t}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

which is Helmholtz's equation.

These results of the second law of thermo-dynamics are of course not to be applied to any real cells, except so far as they approach the condition of reversible action. They give, however, in many cases limits on one side of which the actual values must lie. Thus, if we set $\leqq$ for = in equations (2), (4), (5), (6), and $\geqq$ for = in (8), the formula will there hold true without the limitation of reversibility. But we cannot get anything by differentiating an inequality, and it does not appear *a priori* which side of (10) is the greater when the

Digitized by Google

condition of reversibility is not satisfied. The term $\frac{Q}{t}$ in (11) is certainly not greater than $\eta' - \eta''$, for which it was substituted. But this does not determine which side of (11) is the greater in case of irreversibility. It is the same with Helmholtz's method of proof, which is quite different from that here given, but indicates nothing except so far as the condition of reversibility is fulfilled. (See *Sitzungsberichte, Berl. Acad.*, 1882, pp. 24, 25.)

I fear that it is a poor requital for the kind wish which you expressed at Manchester, that I were present to explain and support my position, for me to impose so long a letter upon you. Trusting, however, in your forbearance, I remain yours faithfully.—J. WILLARD GIBBS.

ON THE EFFECT OF LIGHT ON THE ELECTRIC DISCHARGE.*

BY E. WIEDEMANN AND H. EBERT.

Prof. H. Hertz, in a recent paper† on the effect of the ultra-violet rays on the electrical discharge, describes a series of investigations, showing that light rays have a certain influence on the passage of the electrical spark. This he found to occur exclusively in the case of the extreme ultra-violet rays. It was not determined whether this effect was caused directly by the action of the light, or was due to some other action, which was itself caused by the light rays. To gain a further insight into the matter, we first repeated the experiments of Dr. Hertz with perfect success, and then extended them further, with the following results. The source of light was always an arc lamp, but magnesium was used in a few of the earlier experiments.

1. The phenomenon occurs with the greatest regularity, not only when an induction coil is used, but also with a Holtz machine. In this case the spark under observation was arranged as a shunt on a spark micrometer, and the effect of light falling on the spark region was to lower the potential required to produce it.

2. In order to study the effect of the light rays during the passage of the electricity through the (passive) spark region, one pole of the machine was joined to earth, while the circuit from the other pole was first through the spark region, and thence either through an ordinary Geissler's tube, or through a rubber-cased telephone to earth. The effect of light falling on the spark was to change not only the note, but the whole character of the sound heard in the telephone. In the Geissler's tube the discharge, which was intermittent when no light fell on the spark, became steady and continuous. This was also very noticeable in the spark itself. All this, however, *only* took place when the negative electricity passes through the spark region. Where the positive passes, no difference was noticeable whether the spark region was illuminated or not. Care should be taken to avoid reflections of the light from the bright knobs and metal work, as they might interfere with the true phenomena. Inductive effects from the electricity accumulated on the knobs must also be prevented. If these precautions are taken, then if, with an illuminated spark (under atmospheric pressure), a certain note is heard in the telephone, it will be found that, when *no* light falls on the spark region, a buzzing sound will be heard, through which may be detected a very much deeper note. This, however, is only when joined up with the *negative* pole. With the positive there is *no* difference. The difference in the spark itself is also very noticeable. Without illumination, the path of the spark is irregular, and constantly changing in form and position, and owing to the persistence of vision, there appear to be several sparks at once. The moment the first ray of light falls on the spot at which the negative electricity enters the spark region all these paths close up into a single one along which the current flows perfectly steadily and evenly, and without the noise which accompanied the discharge when unilluminated. At both balls the discharge is perpendicular to the surface.

3. The intensity of the action of light on the −E depends very considerably on the pressure of the gas in which the discharge takes place. It reaches a maximum at a certain pressure and for a certain distance apart of the balls, and rapidly falls off if this pressure be either increased or diminished.

4. The source of light used is of great importance. The phenomenon shows itself best with light from the hottest part of the electric arc. The beam must strike accurately on the spot where the spark leaves the negative ball; the other ball should be shaded for the reasons already mentioned.

5. The phenomenon takes place in dry or damp air, in dry or damp hydrogen, and in carbon dioxide; in the last it is especially noticeable. The pressure at which the maximum effect is obtained varies with different gases; it has apparently a very close connection with the development of the cathode ray.

6. The phenomenon is not entirely dependent on the ultra-violet rays. This is best observed in an atmosphere of carbon dioxide, either dry or moist. Here rays which distinctly belong to the visible part of the spectrum have an undoubted effect. With the ultra-violet already cut off by a glass plate held in front of the light, a most distinct difference was observed if the more refrangible *visible* rays were cut off by further interposing a plate of red or green glass. Blue glass allowed a considerable proportion of the active rays to pass. That the effects were not caused by heat rays was proved by the fact that the interposition of a plate of alum, or a glass cell containing a solution of alum, did not interfere with the effect. It is as well to remember that the light at the cathode in carbon dioxide is of another colour to that in hydrogen.

The phenomenon occurs also in air when the ultra-violet rays are cut off, though not in such a marked degree.

7. From our experiments, and especially bearing in mind that it is only the negative electricity which is affected by light, we have come to the conclusion that there is a very close connection between the phenomenon and the production of the ray from the cathode (Entwickelung der Kathodenstrahlen.) Through the action of the light falling on the electrode the conditions of the production of the synchronously vibrating rays from the cathode is facilitated. Since the wave lengths of these rays are different in different gases, it follows that there must be for each gas a portion of the spectrum of various wave lengths which has more effect than the rest. The production of the cathode ray depends, further, on the pressure, but differently in each gas; consequently, the magnitude of the effect of light should depend on the pressure. It is, in fact, a sort of resonance phenomenon, and is in some degree comparable to explosion of substances which can only be brought about by the prior explosion of certain other substances. The cathode rays clear the way, as it were, for the discharge which follows.

REVIEWS.

The Journal of the Society of Telegraph-Engineers and Electricians.

The sixty-eighth number of the *Journal* of this society is just issued, and contains the paper on "Deep Sea Sounding," by Mr. E. Stallibrass, the paper of Dr. Fleming, and that of Profs. Ayrton and Perry on "New Types of Voltmeter," together with the discussions which followed. There is also an original and important communication from Mr. A. E. Kennelly "On the Superiority of the 'Earth-Overlap' Method in Localising Small Faults in Submarine Cables when no Loop is Available." The abstracts from foreign periodicals are a well-chosen selection, and complete a number of unusual interest.

The sixty-ninth number of the *Journal* has followed closely upon its predecessor. This issue is made up of the report of the discussions on the papers on voltmeters, by Dr. Fleming and Profs. Ayrton and Perry; the proceedings of the sixteenth annual general meeting of the society, which took place on December 8th, 1887; and the paper by Mr. A. C. Cockburn, on "Safety Fuses for Electric Light Circuits, and on the

Digitized by Google

Behaviour of the various Metals usually Employed in their Construction." This paper is fully illustrated, and contains the record of a valuable series of experiments, which were evidently carried out with considerable skill and care.

Transactions of the American Institute of Electrical Engineers.

With the December issue of the *Transactions* of the American Institute of Electrical Engineers the Institute commences the publication of an index of current electrical literature. The present instalment dates from October last, and contains references to more than 300 distinct articles, cited from about 50 journals, mostly of American origin. Subsequent issues will, we are informed, comprise the leading electrical publications in foreign languages. We have quite recently noticed the first issue of a German periodical, to appear quarterly, devoted to the same purpose, and publications of a somewhat similar character have long been issued in the French language, but nothing of the kind has hitherto appeared in English, and the Institute will deserve the thanks of every English student of electrical literature.

The present issue of the *Transactions* appeals exclusively to the Submarine Cable interest; it contains a paper on "Recent Improvements in Apparatus for Ocean Cabling," by Mr. Charles Cuttriss, one on "The Siphon Recorder and Ocean Telephony," by Mr. J. D. Lockwood, together with the discussion thereon. These papers are each of considerable interest.

THE PATTEN ELECTRIC MOTOR.*

We illustrate herewith an electric motor of novel construction invented by Lieut. F. Jarvis Patten, U. S. Army. Its novel features consist mainly in a new system of armature winding, commutators and connections, as well as some mechanical details worthy of notice. In the accompanying engravings, Fig. 1 is an elevation of the motor.

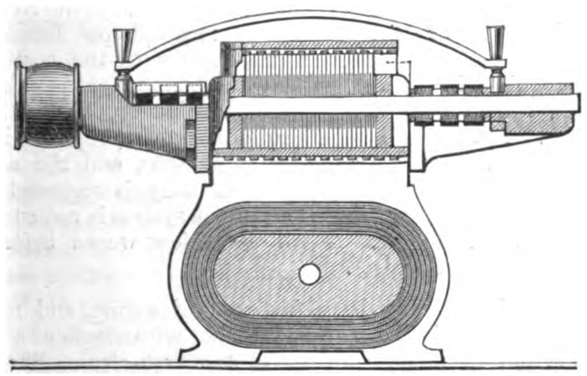

FIG. 1.

A noticeable feature of the machine is an exceedingly short magnetic circuit and a slightly unsymmetrical field, the purpose of which will be explained later. The motor has a comparatively large proportion of iron, a single magnet core and coil forming the yoke of a very short and stout electro-magnet, thus bringing the centre of gravity of the entire machine to the lowest possible point. To the core there is bolted by a single transverse bolt the two curved pole-pieces of cast iron, which are so shaped as to reduce the magnetic lines of force to their shortest length, while the armature fits so closely that there is but $\frac{1}{32}$nd of an inch of air space in the magnetic circuit.

Secured to the spindle is a three-coil armature of peculiar construction. The coils are wound longitudinally around three poles, radiating at angles of 120 degrees from the spindle. The armature may therefore be regarded as a drum armature with three coils and a minimum amount of inactive wire, the ends being shortened in the proportion that the length of a chord of 120 degrees or less is to that of a diameter of the same circle. These three coils of the armature are all continually in circuit in parallel arc, so that the armature consists of a three-coil multiple arc winding, thus reducing materially the armature resistance, as by the peculiar arrangement of the field described none of the coils of the armature are at any time cut out of circuit.

* From the *Electrical World*.

This system of construction admits further of a non-sparking commutator for all positions of the brushes, and is the result of the peculiar commutator connections rendered necessary. These are shown in Fig. 2.

As will be seen, there are practically two commutators, one revolving under the positive and the other under the negative brush, and the two brushes are placed upon the same side of the spindle and at opposite ends of the armature. This arrangement, it will be noticed, leaves the entire commutator exposed, so that it can be easily cleaned while the machine is running. In Fig. 2, the vertical lines E E represent a vertical diameture of the armature spindle, and each segment of the commutator is shown in its proper relative position thereto. An examination of the diagram of connections will show that each of the three coils is constantly in circuit, and is entirely independent of the other two. The action of a single coil during one revolution will therefore describe that of all. Thus, in Fig. 2, the coil A is shown with its terminals connected to two partial commutators, one revolving under the positive, and the other under the negative brush. The coil is secured by one terminal to the segment a^1+, and after traversing the armature has its other end secured to the segment a^1-, which revolves under the negative brush, and occupies exactly the same angular position on the spindle as the first segment. This last segment, however, is also connected by a free conductor r^1r^1 back to the second segment $a^2+$of the first half commutator; and the segment $a^2-$of the second half is likewise connected by the free conductor r^2r^2 back to the short segment $a^1+$of the first half.

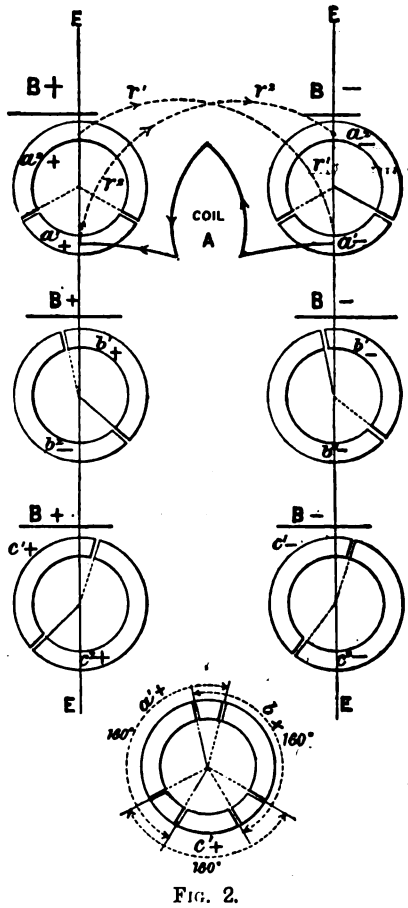

FIG. 2.

The other coils of the armature are similarly connected to their corresponding commutator segments, the only difference being that the corresponding segments for the different coils are placed in rotation around the spindle so that their middle lines make with each other angles of just 120 degrees.

If now the current be regarded as flowing direct from the positive to the negative brush, and the result during a single complete revolution of the coil A be traced, it will be seen that while the short segments $a^1+$and $a^1-$are under their respective brushes the current will flow direct in the coil A from the positive to the negative brush. When, however, the short segments pass out of action the current will flow from the positive brush B+, through the long segment a^2+, the free conductor r^1, over to the short segment a^1- (no longer under the negative brush), then back through coil A in a reverse direction to the short segment a^1+(no longer in contact with the positive brush), and thence through the free conductor r^2r^2 to the long segment a^2-, and out through the negative brush as before.

Digitized by Google

It is therefore plain that the current flows direct in any coil while the short segments are under the brushes, and in a reverse direction whenever the long segments are in contact with the brushes; and this change takes place alike for each of the armature coils in rotation.

The relative amount of direct and reverse current taken in a revolution by each coil will depend upon the relative amount of the spindle circumference covered by the long and short segments, and this must necessarily depend upon the amount of distortion or unsymmetrical arrangement of the field, which, for well-known reasons, must have comparatively narrow limits. This distortion of the field amounts practically to changing the diameter of commutation from a right line (diameter) to a broken line, consisting of two radii meeting in the centre of the spindle, an effect involving, it is claimed, no disadvantages under the conditions as secured and provided for, viz., that both brushes are on the same side of the spindle.

If, now, the further condition be borne in mind that the coils must of necessity radiate at equal angles of 120deg. from the spindle, and we give to the field-poles a relative position, as shown, such that the points on the armature circumference where the current must change direction are at the extremity of radii that are inclined at some angle between 140 and 160deg., it will result in giving to the armature a continuous unbroken circuit, and as the three coils are always in parallel arc, there can be no short circuiting of the coils due to the brush bearing upon two different segments simultaneously.

This effect is shown by the lower diagram in Fig. 2, in which the short segments are shown as covering arcs of 160deg. each of the spindle circumference. Any two successive ones must therefore overlap by an angle of 20deg., from which it results that there is no point during a complete revolution at which the armature circuit is broken. For, as the current changes from any one coil at any point, there are two others in contact with the same brushes that form a continuous circuit. The resultant effect amounts practically to making a set of commutator segments that cover $3 \times 160 = 480$ degrees, each single part overlapping the other by an amount equal to $\frac{1}{3}(160-120) = 20$ degrees.

Another result of this peculiar form of armature construction is the complete elimination of a dead centre, there being at all points of a single revolution a continuous rotary torque, which may be expressed as the resultant effect of three separate tangential efforts which can never be so placed as to neutralise each other.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *Jan.* 21*st*, 1888.

It looks as though murderers in the State of New York will hereafter be executed by electricity. In 1886 a Special Commission was appointed by the Legislature to report on the most humane and practical methods known to modern science of carrying out death sentences in capital cases. After an exhaustive inquiry the commissioners have reported in favour of electricity. Their report is quite voluminous. It is in many ways a valuable document, and is probably the most complete treatise on the subject of capital punishment now extant or of any utility. The commissioners have inquired into and enumerated specifically the various modes of punishment that have been in vogue in times past, or are now practised. The various objections to the most likely methods are considered, and the views and opinions are given of a large number of judges and judicial officers. To the electrician the most interesting part is that which deals with electricity, which the commissioners speak of as "the most potent agent for destroying human life;" and among the authorities cited on the subject are Prof. Helmholtz, Prof. Tyndall, Mr. Edison, and Prof. Elihu Thomson, the last two of whom contribute their views, which are printed in the report. The commissioners recommend that the current shall be administered to the criminal by means of a chair, with a head-rest and foot rest, and that the current should be obtained from any local electric light plant, or, if desirable, from an independent machine in the prison. It may be noted that Prof. Elihu Thomson objects to the use of a chair, and recommends, as the most certain way to produce death, the passage of the current down the spinal chord from the crown of the head by the application of wet surfaces or sponges. As an illustration of the manner in which the electric system would work, the commissioners instance the wholesale destruction of dogs carried on at Buffalo last year at the dog pound in that city. In this case, as you may perhaps have noted at the time, each captured cur was placed in a pine box, lined with zinc, and partly filled with water, and his nose was fitted into an iron or copper muzzle. Current was then turned on and the death of each dog was instantaneous. In order to deprive the criminal of any of the cheap and hideous glory that now attends an execution, the commissioners propose that electrical executions shall take place in private, and that even the day of death be made uncertain. The Bill incorporating the recommendations of the commissioners will, if it becomes law, take effect on January 1st, 1889; and as the public sentiment is generally in favour of the new system, it is likely that, in New York State at least, electricity will be made the means of inflicting the most dreadful sentence of the law. I believe that some action of the same kind has been contemplated in Pennsylvania, where a chair for electrical executions has been submitted to the notice of the Legislature. It seems not improbable that New York will take the initiative in this matter.

Another week has come and gone, and still we have no decision from the United States Supreme Court in the Bell Telephone case; in fact, it is now reported that the Court may take a long adjournment—until March—before presenting its verdict. With so much at stake it need hardly be wondered at that the anxiety felt in some quarters is very keen. The richness of the prize becomes more tempting every year. In 1887 the parent company earned 22½ per cent. on its £1,960,000 capital; in 1886 the earnings were about 20 per cent., and in 1885 they were 18 per cent.

You in England are tolerably familiar with petitions that bear miles of signatures, and we now have something of the same kind here in the monster memorial to be presented to Congress by the Knights of Labour in favour of Government telegraphs. This movement was started some little time ago, and was then mentioned by you. The petitions are now being returned to the Knights' head-quarters in Philadelphia. The first batch was received on January 3, when two trips of a mail delivery waggon to the post office were required in the morning and another at night to clear the boxes; while a large number of bulkier packages came in by express. Mr. Powerby, the head of the order, rejoices in the possession of about half a-million autographs, and the energy that has been shown throughout the body is regarded as a sign that the feeling against the present system is not confined merely to the leaders. It will be a few weeks before the petition reaches Congress.

Chicago has already been favoured of nature and man in many ways, and is about to add to her advantages as a commercial and manufacturing city of the first class. She is to have her own supplies of oil and natural gas, and will not have to go far for either of them. It was proposed to pipe gas for the Indiana wells 150 miles off, but gas has now been struck not only in East Chicago, but in the heart of the city; and the supply of gas and oil at East Chicago promises to be "inexhaustible." The ingenious proposition is made to run the oil and gas thence into the city in one and the same steel pipe, the gas furnishing the pressure. Arrived at Chicago, each would run into its own receiver to be stored or used. The interest in this matter to electrical engineers is that a stimulus to electric lighting is expected if the discovery proves as valuable as it now promises to be. With natural gas at 10 or 15 cents per 1,000ft. it would be easy to manufacture current very cheaply for light and power, and that is the view taken in electrical circles in Chicago.

The decision against the French Cable Company by the Tribunal of Commerce cannot be said to have been unexpected here, one ground of belief being that great care was taken at the time the arrangement was made to have it as valid and binding as possible. It is rumoured, by the way, that higher cable rates are near at hand, and there has been some little discussion as to the effect of an outbreak of war in Europe on

Digitized by Google

the cable situation. Such a war would add tremendously to the volume of business, and might lead the companies to a better tariff simply to keep business within bounds. I do not think the staffs of the various companies view low tariffs with the slightest degree of approval.

CORRESPONDENCE.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS AND THE PARIS EXHIBITION OF 1889.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am instructed by the President and Council of the Society of Telegraph-Engineers and Electricians to request the favour of your giving as early an insertion as possible to the following notice:—

"In view of the interests of English Electrical Exhibitors, the Society of Telegraph-Engineers and Electricians have appointed a committee to endeavour to ascertain their wishes and to make arrangements on their account with the French authorities. The Director-General of the International Exhibition having requested the society to take part in the matter on behalf of the official administration, it is proposed shortly to address a circular to the principal firms interested in electric lighting and kindred pursuits, and to convene a meeting of gentlemen who are likely to take part as exhibitors in the forthcoming display.

"It is of extreme importance to British industries that they should be well represented on the occasion referred to, as without it there is danger of Continental opinion assuming that England has fallen back in the race for success in the alliance between science and commerce."—Yours, &c.,

F. H. WEBB, Secretary.

Society Telegraph-Engineers and Electricians,
4, The Sanctuary, Westminster.

OVERHEAD WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Caws invites attention to the fact that no writer has yet succeeded in sustaining one objection to his spring shackles. He has forgotten my objection that they are utterly useless against the only stresses that break telegraph wires.—Yours, &c.,

W. H. PREECE.

January 31, 1888.

INDIA RUBBER COMPENSATORS FOR OVERHEAD WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. Caws, I would refer him to my remarks in *The Electrician* of the 6th inst., that "the table could be amended, as found by experiment to be of the greatest advantage, by altering either the quality or the thickness of the india rubber."

If (as Mr. Caws states) I should have to multiply by 16 the weight of my india rubber, my compensator would in that case have almost the same disadvantages as the springs which I abandoned as useless for the purpose. I agree with Mr. Caws that I should not improve the insulation by cutting the wire at each post, and do not propose to do so; in fact, that is one of the great features of my plan. I do not remove the old insulator from the line, but withdraw the bolts and substitute my compensator for the ordinary two strips of the shackle. As far as the insulation is concerned, it would remain exactly as it is at present.

To conclude, I should much like to know how Mr. Caws proposes to protect his springs from the weather, and especially the gases in the air over large cities. Does not the process of galvanising eat through the surface, thereby making the spring perfectly useless unless applied considerably over the size and strength theoretically specified? I cannot say I have had seventeen years of experience and study, but as an engine fitter at Messrs. Maudslay, Sons and Field it must be admitted at least I am practical, and my opinion is that there is nothing at present so well suited for compensating overhead wires as india rubber.—Yours, &c.,

R. S. BOZON.

January 30th, 1888.

THERMO-ELECTRICITY.

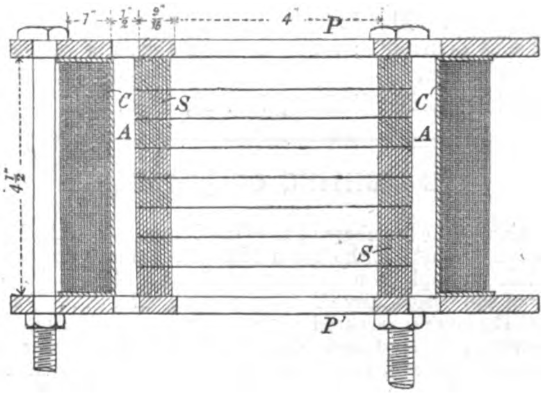
TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your account of Mr. Acheson's experiments in this week's *Electrician* are interesting to me, as I trod the same or similar ground only a few months ago.

Some desultory experiments I was making with a spiral of iron wire gave results which recalled to my mind the discovery by MM. Hinghausen and Nerust announced in *The Electrician* last February; but the effects I observed were much stronger than that announcement would lead one to expect. I felt impatient to test the practical utility of the effect, and forthworth set about the construction of an apparatus for the purpose.

The view I took of MM. Hinghausen and Nerust's discovery was as follows:—As in ordinary magneto-electric induction we have three actions, each of which must be inclined to the plane of the other two, giving maximum effect when the direction of motion is perpendicular to the lines of force, and also to the path of the current, so the best conditions for this new effect are fulfilled when the thermal current, the lines of force and the path of the current are each at right angles to the others.

Now, if a conductor be traversed at right angles by lines of force and by a thermal current at right angles both to the conductor and the lines of force, any given length of it will develop a certain E.M.F. depending upon the strength of the field, the thermal current, and upon the nature of the conductor. Similarly, any other equivalent length of the conductor will develop this E.M.F., so that the aggregate E.M.F. will *cæteris paribus* be proportional to the length of the conductor, and the quantity will obviously be proportional to its sectional area.



Upon this principle I constructed a pile of iron spirals, S, made of iron tape $\frac{9}{16}$in. wide and $\frac{1}{16}$in. thick, connected in series, and containing a total length of 80ft. Wrought-iron plates, P P, $\frac{3}{8}$in. thick, formed the pole-pieces, and a circle of $\frac{1}{4}$in. holes were punched in each, opening into the annular space A, between the outside of the iron spirals and the copper exciting coil C. The side bolts held the whole together. The interior of the iron spirals could then be heated by means of a spirit lamp, a porcelain cell being fixed in the centre to compel the draft to move over the inner surfaces of the iron.

The exciting coil was connected to the screws of a good-sized bichromate cell. When the outside of the iron spirals became hissing hot, and a powerful cooling draft rose through the annular space, showing that a good thermal current was flowing at right angles to the conductor and to the lines of force, the effect from these 80ft. of $\frac{9}{16}$in. by $\frac{1}{16}$in. iron tape,

Digitized by Google

whose terminals were connected with a reflecting galvanometer, was not quite, but *almost absolutely, nil.*

Care was taken to guard against ordinary thermo electric effects, and the strength of the field was tested roughly by connecting each spiral separately with the galvanometer through a resistance and observing the extent of the first swing at making or breaking the exciting circuit, and it was found that the 11lb. of copper wire used gave a pretty strong field. I remember doing this also when the iron coils were hot, when I should, according to Mr Acheson's observations, have observed an enhanced induction. Such was not the case.

I give this bit of experience for the benefit of any of your readers who may be tempted to exercise their ingenuity upon the discovery of MM. Hinghausen and Nerust.

I was taken aback at the result of my investigation, and returned to my original experiments tosee what was the matter, and found that in the first instance I had made a grave mistake by regarding a spiral of galvanised iron wire as iron wire, there being a remarkably strong variation in the thermo-electric strength of different parts of the wire, so that certain points in it were equivalent to ordinary junctions of dissimilar metals, and that insufficient provision against chemical effects in subsequent hastily conducted test experiments gave a series of remarkable fortuitous coincidences in the results, each corroborative apparently of the fundamental assumption which gave me a false impression of its importance.

But for MM. Hinghausen and Nerust I had been less precipitate.—Yours, &c., R. SNOWDON.

Stavely Ironworks, 27th Jan., 1888.

SAFETY FUSES WITH SPRINGS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your notice of a paper by Mr. Cockburn on safety fuses, one is mentioned as designed by Sir W. Thomson, consisting of springs, united by a button of fusible alloy, which fly apart when the alloy melts.

This, I believe, is the subject of a patent by him. I believe, however, I am correct in saying that a patent for exactly the same thing, and taken out by Mr. Boys and myself, is some years prior. I have no doubt that the inventions were entirely independent, and though I believe that neither Sir W. Thomson nor ourselves have ever caused them to be commercially manufactured, yet our experiments have shown that the matter is worth pursuing. The difficulty is to make them uniform when used for small currents; for large ones they are very satisfactory.—Yours, &c., H. CUNYNGHAME.

Hurlingham Lodge, Fulham, Jan. 27, 1888.

THE LIGHTING OF BRADFORD.

A meeting of the members of the Gas Committee of the Bradford Corporation was held at the Town Hall on Friday last to confer with Dr. J. S. Hopkinson in reference to the electric lighting of portions of the borough by the Corporation. Mr. J. N. Shoolbred, M.Inst.C.E., having prepared a scheme upon a basis suggested by the committee, it was thought desirable that an eminent authority on such matters should be called in with a view of some feasible scheme being adopted. Dr. Hopkinson, accompanied by the members of the committee, examined various sites for the necessary plant required in carrying out the suggested scheme, and concurred in the view of the committee that certain land belonging to the Corporation, in Bolton-road, was the most suitable. As to the area to be supplied with the electric light, it was thought desirable that an installation be laid down, on the site suggested, of sufficient power to supply the central portion of the town, lying in the vicinity of Kirkgate and Market-street, as already approved by the council, to be on the low-pressure continuous-current principle. As a result of the interview, it was ordered that a specification of the proposed works should be prepared by Mr. Shoolbred, to be submitted to Dr. Hopkinson; and this being approved, the works will be let by tender. The specification will be framed to give an opportunity to the council to secure the best electrical appliances possible, compatible with the cost being brought within the sum of £15,000 proposed to be expended by the Corporation as a first outlay; the works to be so arranged that, if deemed necessary, they may be extended in accordance with the wishes of the council.

SOCIETY OF TELEGRAPH-ENGINEERS.

At the ordinary weekly meeting of this society on Thursday evening, the discussion on Mr. A. C. Cockburn's paper on "Safety Fuses for Electric Light Circuits" was proceeded with.

The President (Mr. Graves) was in the chair, and there was a good attendance.

[Before giving our report of the discussion we may refer to the adjoining figures, which illustrate the type of fuse introduced by Mr. Cockburn. Fig. 1 shows the fuse of lead wire, with the pellet of lead attached to the

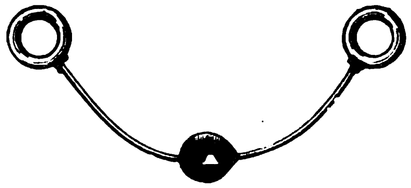


FIG. 1.

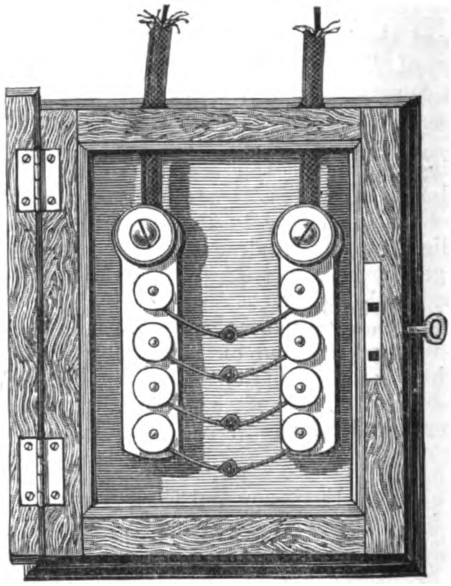

FIG. 2.

centre. Fig. 2 shows the compound fuse as employed for main leads carrying heavy currents.]

Prof. S. P. THOMPSON said he had been cognisant of the experiments of Mr. Cockburn during the whole time they had been going on. Referring to the fact that it required a larger current to produce the same result when the wire was short, Mr. Cockburn said one inch and a-quarter should be the length for the fuse, but he (Prof. Thompson) did not know whether he meant that as a dogmatic statement. If they had thin terminals an inch would give more than sufficient length. It was a question for experiment what was the best length under any given conditions. It was clear, however, they could not have very small terminals; they must have them large enough to be able to attach the fuse to them with comfort. It would not do to have microscopic screws. The conductivity of the material of which the terminals were made would have a great deal to do with the question. If copper was used there would be a certain cooling effect; if brass terminals were used it would be less, as brass was a worse conductor of heat than copper. He had never heard of any fuse before that could be relied on to melt with a current the strength of which was within any thing like three per cent. of the current it was supposed to go off at.

Mr. K. HEDGES wished to point out that Mr. Cockburn's novel application of fuse was not new. He used apparatus some years ago designed on the same plan. It appeared to him that Sir W. Thomson had really done everything that had been put forward in the paper. He would read his description of the fuses:—"The essential conditions fulfilled in the construction of these fuses are—(1) certainty and uniformity in action, (2) smallness in the percentage loss of energy in the fuse itself, (3) facility in replacing a fresh fuse. These objects are attained by making the fuses of two springy pieces of high conductivity copper, in which heat due to the current is generated, and uniting them by a soldering of fusible metal which melts at a very moderate temperature. The copper springs are made of such form and are so placed as to give complete severance of the circuit with instantaneous stoppage of the following arc when the melting of the fuse has taken place. The fuses are of two kinds—the spiral fuse, which is the form of fuse designed for currents of from ten amperes down to a half ampere, and what is called the Z fuse, on account of the similarity of its shape to the letter Z, is designed for any current of from six amperes upwards to hundreds or to thousands of amperes." Spiral fuse: In a spiral fuse two spirals of copper are used. The outer

Digitized by Google

ends of these spirals are fixed to copper caps closing the ends of a containing tube of glass. The inner ends are soldered together with fusible metal. If the copper wire becomes overheated the fusible metal melts. The spirals then contract in opposite directions and the circuit is broken. The glass case of fuses of this class may be returned to the maker when the fuse has been melted in order to have the fuse restored. The Z fuse consists of straight pieces of copper wire with two extremities, soldered together by fusible metal and with the other ends bent into loops, which guide the fuse into position in the fuse-holder. The fuse-holder is a box lined with slate or mica, at the ends of which are two binding clamps so placed that the screwing up of the clamping screws puts a double bend into the otherwise straight fuse. In consequence of this bend the two parts of the fuse spring together as soon as the current exceeds the prescribed amount. The great point about Sir Wm. Thomson's fuses was the question of the loss of energy, and in a letter to him (Mr. Hedges) he had put it at a quarter of a watt for 12 amperes of current. The results of other experiments were much higher than that, probably because of the difficulty of making a good connection with the fusible wire and the terminal. His (Mr. Hedges) experiments showed about one watt per six amperes. As regards the accuracy of the foil, he thought it was a question of coating the foil to the right size and using it in the proper way. He could not see why fuses should not be made under certain circumstances to protect lamps. He thought this discussion should raise the very important question of the margin to be given to fuses. He quoted from the eleventh edition of the Phœnix rules, to show that the two constructions given did not agree. A rule said 50 per cent. should be allowed for cut-outs, and then further on, for double table cut-out, 25 per cent. The old rules of the Telegraph-Engineers said the fuse should be arranged so that no part of the system should obtain a temperature of 150deg. F. He did not understand what that meant. It must be a very fusible metal to go at 150deg.

Mr. Preece said this was a subject to which he had devoted a very great deal of attention, more from a scientific aspect than a practical one; although he was bound to confess he had had a considerable amount of experience in the defects as well as in the advantages of cut-outs. Mr. Cockburn's paper was, so far as he could remember, the first systematic effort to draw what had been rather in a state of chaos into something like a scientific position. Mr. Hedges had said there had been other workers in the field. They knew Mr. Edison was the inventor of cut-outs, but he was afraid that because he did not patent it he had not received sufficient credit for being the originator of this system. It had also been pursued by Mr. Hedges, and he did not hesitate to say that his form of fuse had been one of the most useful that had been in the market. He had used it for the past four years in his house, and he had derived considerable benefit from its proper behaviour at the right moment. Again, Sir Wm. Thomson had devoted a considerable amount of attention to the matter, and his fuse was certainly most efficient, and extremely pretty in its form. He was very much inclined to think that this question of cut-outs was very much overdone. They had cut-outs forced upon them in all directions. They must remember this, however perfect a cut-out may be, it also brought with it its own defects. One building that he had something to do with had so many cut-outs in it that he found on going into the matter that the cut-outs themselves had introduced no less than six thousand bad joints [laughter], so that they had not only these cures producing their faults, but also their dangers; and he should say that out of every ten failures of electric lighting that he had had to inquire into nine had been due to the failure of cut-outs [hear, hear]. The whole question had now been thoroughly and efficiently thrashed out. In 1884 he read a paper before the Royal Society on the heating effects of electric currents, and the origin of that paper was that they protected, and had done so for the last twenty years or more, all their submarine cables from the dangers of atmospheric electricity by supplying them with a cut-out. At the end of every cable there was a lightning protector in the form of plate and a vacuum tube, and in addition they also inserted a fine piece of platinum wire, which should fuse before the current could acquire sufficient strength to be a danger. It became a matter of great consequence to know what should be the proper size of this wire. There were currents induced by atmospheric electricity that exceeded very little the strongest that were used in actual work, and therefore it became desirable to have such a cut-out that should not fuse with the most powerful working current until that current was exceeded by some 50 per cent. He made a series of experiments, and it proved the law that had been originally published by Mr. Kempe, and developed by Prof. Forbes

$$C = d^{\frac{3}{2}} \times a.$$

His first experiments were devoted to proving the accuracy of that law, and while they did show that below a certain size when the wire was very fine the law was not verified, when they came to wires of 10 mils and beyond then the law was strictly and absolutely true (hear, hear.) Now, having shown that law to be true from platinum, it became desirable that they should know how far that law was true for all sizes and for all wires. During the past twelve months he had been engaged in determining the value of the constant a for all metals, and in his paper in 1884 he pointed out the error that might arise from the cooling effect of the mass of the terminals. He showed that when they used lengths of six inches they were outside that error, so that all his experiments were made with lengths of six inches. In a paper which he had lately sent to the Royal Society, but which had not yet been published, he had taken two cases—one where the length of the wire was only an inch and a-quarter—that being the minimum length for cut-outs, and in the other the lengths were six inches, and he took three fiducial points. He wanted, if he could, to determine a current that would raise a wire to a certain temperature. The rule of the Telegraph-Engineers implies that leads and mains should never be designed so that when the maximum current passes through them their temperature is raised to 150 deg. The point he took for observation was the point when the wire reached a sensation of warmth. He found that the sensation of warmth was extremely uncertain, and in order to avoid being dependent upon the very sensations that different observers found he used a thin flake of shellac, and when that wire acquired a temperature of 77deg. Centigrade that shellac melted. The second fiducial point was when the wire became red hot. The wire became just visibly red always at the same temperature. The third fiducial point was the fusing current. Taking these three points, he used copper, aluminium, platinum, German silver, platinoid, iron, tin, tin-lead alloy, and lead, and for all these materials there were various sizes, commencing at 10 mils and going up to 40. The measurements were given in inches and in centimetres, and the gauge of the wire was given, and for all these wires, and for all these results the constant a has been calculated. In these experiments a very curious thing came out, viz., that shellac acted as a kind of flux and prevented the oxidation of the metal, so that his shellac flake acted in almost the same way as Mr. Cockburn's little lead pellet, and the result was that it always went with 25 per cent. less current than when there was no shellac at all. Another interesting fact came out—viz., that these three fiducial points in the case of platinum were separated by temperature in the ratio, roughly, of 1, 2, 3, so that if they had a piece of platinum wire and a current of temperature which would melt shellac, twice that current would make it red hot, and three times that current would fuse it. The third series of experiments were made to determine what took place when they had a sudden short-circuit, throwing on to the leads a sudden current, and resulting in a sudden burst up of the cut-outs. It was very important to know how the different metals behaved themselves under different circumstances when a current of great strength was passing through them. He took tin, platinum, silver foil, silver wire, zinc foil, zinc wire, copper, &c., in fact, everything he could get hold of, and in the result he found that the best metal to meet such a case was platinum. It went off like wax; it did not burst from explosion, but went off gently. Tin was good in itself, but the other things scattered the molten particles about, and were really extremely dangerous to use. When they remembered the great variation in the gauge of wires and the different qualities that existed, it was not surprising that cut-outs varied from 5 to 10 per cent. from the figures attached to them. If they got within 10 per cent. they should be satisfied. His own impression was that they had got to 10 per cent. His great objection to cut-outs was the multiplication of bad joints. Every single screw was a loose joint, and sooner or later was certain to produce a fault. Mr. Preece strongly recommended the use of platinum for small cut outs as being cheap, never oxidising, and being capable of being screwed under a nut and remaining there for a long time in a perfect condition.

Prof. Ayrton confirmed the view of Mr. Preece with regard to the testing of the law stated by Mr Kempe and developed by Prof. Forbes.

Sir David Salomons said most of the experiments given had been made for laboratory purposes, and had to be verified in practice. Nothing had been said as to how metal acts under direct and alternating currents. He could not answer the question himself, but put it to gentlemen who could. He would like to hear how the experiments were conducted by Mr. Preece and Mr. Cockburn, and also how long these fuses which were experimented upon were used. He maintained that a fuse made to-day to go at five amperes would not necessarily go at five if it had been in use for a long period. The fuses brought out had not always been very successful. He had used Mr. Hedges', and sometimes it had been a success and sometimes a failure. Mr. Cockburn threw over, not intentionally, but in a rather cavalier manner, certain magnetic switches made by Woodhouse and Rawson. These had been made by a gentleman who had recently joined the society, and he (Sir David) regretted he was not present to defend his interests. Of all the fuses he had ever used this was the only one that would go off at what they set it at, and it had really been invaluable to him. The reason lamps had to be protected was chiefly because they had been badly made.

Mr. Crompton said his firm had been making fuses many years, and they had got fuses in their earliest jobs which were serving their purpose now just as well as when they were first used. They found tin wire good enough for their purpose then, and with all deference he thought it was good enough for their purpose now. Tin wire put in five years ago was still unoxidised, and they did not want anything better than that. A practical question was where to put the fuse. If it was very desirable to get alongside the switch, it would be nice to have them there, but unfortunately that was not the place for the fuse. The proper place for the fuse was evidently as close as possible to the root of the branch where it left the main circuit. His experience was that there was nothing better for cut-outs than hard wood—boxwood or beech was the best. Slate was by no means a satisfactory material for the purpose. He had known a case where the substitution of slate for wooden bases for switches had reduced the insulation resistance of an installation from 12,000 ohms to 600 ohms. Slate varied very much in its insulating properties. There was more nonsense talked on this subject than anything else. The "precautions against the danger of fire" had made electrical engineers to appear very ridiculous (hear, hear).

After a few remarks from Mr. Bernstein,

Mr. Blakesley criticised some observations of Mr. Preece. He hardly agreed with giving preference to the use of shellac as a flux. He would prefer the foil to the circular wire. He emphasised the very important point touched upon by Sir David Salomons with regard to the uniformity of the current employed.

Mr. Parkinson was very much in sympathy with what had fallen from Mr. Preece and Mr. Crompton as to the use of fuses. He thought it was over-

Digitized by Google

done. He knew a case within his own experience in which the hard wood casing, such as Mr. Crompton had described, would have served the purpose as well or better than slate.

Mr. Crookes mentioned an experimental cut-out in which advantage was taken of the thermo-magnetic properties of nickel. An electro-magnet was provided with an armature consisting of a thin strip of nickel, through which the current passed. When the temperature rose to 300deg. C. the nickel lost its magnetism, and was pulled back by an opposing spring, thus breaking circuit.

Mr. Esson endorsed all Mr. Crompton had said with regard to non-inflammable cases. There was more nonsense talked about the firing of cores than any other subject whatever. He saw no necessity whatever for placing even switches on a non-inflammable base so long as they had a proper spring. These restrictions imposed upon electrical engineers were very cumbersome to them [hear, hear].

Mr. Mordey agreed with Mr. Crompton as to the unsuitability of slate. It was not a nice substance to work, and they had found at the Brush works that it was not a trustworthy substance for high-tension working. However, he had got over this difficulty by putting it in melted paraffin. It then made an excellent insulating material. Mr. Mordey paid a warm compliment to Mr. Cockburn for his exhaustive and instructive paper.

Prof. Fleming said that many varieties of slate were impregnated with oxide of iron to such a degree that it was no wonder that their insulating qualities were greatly reduced; but some varieties, on the other hand, possessed a very high specific resistance.

Mr. Hancock having said a few words, Mr. Cockburn replied at some length on the whole discussion, and was warmly applauded.

PHYSICAL SOCIETY.

A meeting of this society was held at the Science Schools, South Kensington, on January 28, Prof. W. G. Adams, F.R.S., Vice-President, in the chair.

In opening the proceedings, the Chairman referred to the great loss which the society had sustained by the death of Dr. Balfour Stewart, their late President, and said that his loss would be deeply felt by the whole scientific world.

The following papers were read :—

On the Effect of Magnetisation on the Thermo-Electrical Properties of Bismuth. By Mr. Herbert Tomlinson.

It has been shown by Sir. Wm. Thomson and others that the electrical resistance of an iron wire is increased when magnetised longitudinally, and similar phenomena were shown to occur in steel, nickel, cobalt, and bismuth, in a paper communicated to the Royal Society in 1882 by the author. On comparing the results, it is found that for the same intensity of magnetisation the increase of resistance of bismuth is about two thousand times that exhibited by iron. The author believes the increase of resistance of bismuth to be partly *apparent* only, and thinks that some influence similar to an opposing E.M.F. is operative, but as to its exact nature he can say nothing. Hall's phenomenon suggests itself as a possible explanation, but experiment shows that this is not the true cause. The change of dimensions due to magnetisation is found to be too small to produce the effect, and, so far, no satisfactory explanation been found. On heating a rod of bismuth, when under the influence of magnetising force, an E.M.F. is set up from unmagnetised to magnetised across the hot junction, having a value of about ·0022 microvolt per 1deg. C. difference of temperature, when the magnetising force was 226 C.-G.-S. units. Ettinghausen has found that a difference of temperature is produced between the two sides of a plate of bismuth placed in a magnetic field, when an electric current is passed through it; and it has also been shown that if a thermal current be substituted for the electric current, a difference of potential is produced.

On the Influence of Magnetism and Temperature on the Electrical Resistance of Bismuth and its Alloys with Lead and Tin. By M. Ed. von Aubel. An abstract was read by Mr. Baily.

Some specimens of bismuth show an increase of resistance with temperature, whilst others shew a decided decrease. M. Righi is of opinion that the decrease is due to the presence of tin, but the author's experiments on alloys show that this is not the case. Magnetism always produces an increase of resistance, but its influence diminishes as the temperature rises. It is concluded that the cause of the anomaly is still to seek.

On a Water-Dropping Influence Machine. By Prof. S. P. Thompson, D.Sc.

In this apparatus only one jet of water is required, and satisfactory results are obtained without special insulation. It consists of three cylindrical metal vessels hung vertically over each other by silk strings, the highest and lowest being connected by a stiff metal wire. The highest is a small cylinder, open at both ends; the lowest is an open pot, which receives the water. The intermediate vessel is open at the bottom, and is provided at the top with a funnel, fixed so that its central aperture is about the middle of the cylinder. The water jet, which must have a fine orifice, is inserted about half-way into the uppermost vessel.

On the Price of the Factor of Safety in Lightning Rods. By Prof. S. P. Thompson.

It is here shown upon certain assumptions that the factor of safety against fusion varies as—total cost $\times \frac{fs}{\rho d l^2 k}$, where f = temperature of fusion of material above atmosphere, s = specific thermal capacity, ρ = specific electric resistance, d = density, k = cost in pence per lb., and l = length of the conductor. If the total cost and length are supposed to be given, the factor of safety $= \frac{fs}{\rho d k}$. Of the common metals neglecting self-induction, iron has the greatest factor of safety, being more than four times that of copper. Such being the case, the author thinks it desirable that the report of the Lightning Rod Conference be reconsidered.

On the Optical Demonstration of Electrical Stress. By Prof. A. W. Rücker, F.R.S., and Mr. C. V. Boys.

A number of lecture experiments were shown illustrating that electrical stress exists in the dielectric separating two charged bodies. The bodies were placed in carbon bisulphide, between two crossed Nicols, and on electrifying them by means of a Holtz machine light passed through the analyser. Two concentric cylinders gave a black cross on the screen similar to those seen on interposing a plate of some uniaxal crystal, and a model illustrating a charged Leyden jar was shown.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

Note.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

932. R. H. Thompson and B. W. Warwick. London. Improvements in the construction of portable primary batteries adapted to medical and other appliances. January 21, 1888.

933. F. Bosshardt. London. Improvements in contact regulators for electric clocks (L. Bouchet, France). January 21, 1888.

980. W. Balch. Clapton. An improvement for the construction of electric battery cells for lighting or other purposes. January 21, 1888.

981. C. Spratt. London. Improvements in electric "call" signal apparatus. January 21, 1888.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).

Report of the Directors to the ordinary general half-yearly meeting of the proprietors, to be held at Winchester House, 50, Old Broad-street, E.C., this day (Friday), the 3rd inst., at 2 o'clock p.m. precisely:—

1. The total receipts from the 1st July to the 31st December, 1887, including the estimated balance of £18,323. 6s. 8d. brought forward from the last account, are estimated at £113,283. 6s. 5d. This amount, however, is subject to revision upon settlement of the accounts for the year with the Paris-New York Telegraph Company. The traffic receipts show an increase of £9,460, as compared with the corresponding period of last year.

2. The total expenses of the half-year, including repair of cables, &c., as as shown by the revenue account, amount to £49,638. 8s. 1d.

3. Interim dividends of 7s. 6d. per cent. on the ordinary stock and 15s. per cent. on the preferred stock were paid on the 1st November last, absorbing £26.250, leaving an estimated balance of £37,344. 18s. 4d., out of which the Directors recommend the proprietors to declare final dividends of 10s. per cent. on the ordinary stock, and 20s. per cent. on the preferred stock, amounting to £35,000, making a total distribution for the year ended the 31st December, 1887, of £1. 7s. 6d. per cent. on the ordinary stock, and £2. 15s. per cent. on the preferred stock, leaving an estimated balance of £2,344. 18s. 4d. to be carried forward to the next account.

4. The Company's repairing ss. "Minia" has been engaged during the past half year in the repairs of the Duxbury, Brest, and North Placentia cables, which were effected on the 28th August and the 12th and 20th September respectively. The Brest-St. Pierre cable, broken on the 9th November, 1886, at a distance of 600 miles from St. Pierre in 2,750 fathoms, was picked up on the 6th of August, 1887, in 2,300 fathoms, communication being restored on the 12th September as above stated—220 miles of new cable were used in this repair. Considerable damage was sustained by the ship in a cyclone during these operations, involving the necessity of her going to New York to refit. The Duxbury cable was again broken on the 2nd of September off Canso, Nova Scotia, on this occasion by the ss. "Pouyer-Quertier, which was at the time engaged upon the repair of one of the Commercial Company's cables. That company at once gave orders to the master of the "Pouyer-Quertier" to repair the cable which he had inadvertently broken, and the work was effected on the 12th of the same month. During the repairing operations off Valentia, Ireland, in December, 1886, it was found that from the rocky nature of the coast at the landing-place of the cables the shore ends had become so greatly damaged by the action of the sea that their renewal and removal to a more suitable locality was absolutely necessary. New shore ends were accordingly laid into Cooscroom, Dingle Bay, which has the advantage of a sandy bottom. The alterations were carried out in the month of September last without interruption to the communication. The 1873 cable was broken in Trinity Bay, Newfoundland, on December 9, but was repaired within twenty-four hours by the officials of the station at Heart's Content.

5. The Company's system of cables and land lines is in good working order, with the exception of the Brest St. Pierre cable, which the Directors regret to report was again broken on October 4 last, at about 1,034 miles from Brest, in a depth of 1,500 fathoms, and at a distance of 1,000 miles east of the previous break. The ss. "Minia" will proceed to the repair of this interruption in the spring.

6. The action brought by the Company against the Paris-New York Telegraph Company, to compel that company to resume performance of of the joint-purse agreements of 1880 and 1882, which they had ceased to carry out since the 31st December, 1886, was argued before the Paris Tribunal of Commerce on the 12th December last. The judgment of the Tribunal was pronounced on the 9th ult. in favour of this Company, with damages of 2,000fr. per day from 31st December, 1836, to the date of service of the judgment. The Tribunal also condemned the defendants to pay 5,000fr. per day from the service of the judgment, for one month, when the Court will decide as to future damages, unless in the meantime the defendants have resumed fulfilment of the agreements, or obtained from the Courts which, according to their concession, should determine the question, a decision that such agreements are illegal. The Paris-New York Telegraph Company are also to pay the costs of the action. They have announced their intention to appeal.

7. In the autumn of last year lengthened negotiations took place in New York between the Western Union Telegraph Company and the Commercial Cable Company (Mackay-Bennett cables) with a view to the purchase or lease of the latter company's cables. The terms demanded by the Commercial Cable Company, however, were of such a character as to preclude their acceptance. During the progress of the negotiations, the representatives of the Commercial Company threatened that unless their terms were agreed to they would immediately adopt the 6d. rate. It is almost needless to say that the joint-purse companies were prepared for this declaration, as they fully anticipated it when they commenced that rate. The Commercial Company reduced their tariff from 1s. to 6d. per word on the 15th of September.

8. The traffic passing over the lines of the joint-purse companies during the past half year shows an increase of 12 per cent. over that of the corresponding period in 1886, the tariff being the same, viz., 6d. per word—and an increase of 162 per cent. over the same period in 1885, when the tariff was 1s. 8d. per word. The adoption of the low rate by all the companies has resulted in a very considerable augmentation of the total Atlantic traffic, but it is as yet unremunerative.

9. The project of the International Cable Company, which was launched in 1886, for the purpose of laying cables between Europe and North

Digitized by Google

America, &c., *viâ* the Azores, still remains in abeyance. At a recent meeting of the shareholders of that company, it was decided to postpone further action for six months, in anticipation that the low rates of the existing Atlantic Cable Companies would shortly come to an end.

10. In accordance with the Articles of Association two Directors of the Company, Sir Daniel Gooch, Bart., and Mr. F. A. Bevan, retire at this meeting, and being eligible offer themselves for re-election.

11. Mr. Joshua Dean and Mr. Francis Glass, the auditors, also retire, and offer themselves for re-election.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 13th January amounted to £3,879, and to £3,023 for the week ended 20th January.

THE CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY.—Mr. J. H. Buckingham, of No. 93, Wood-street, Cheapside, has joined the board of the Consolidated Telephone Construction and Maintenance Company (Limited).

MEXICAN TELEGRAPH COMPANY.—The gross earnings for 1887 are returned at $267,259, as against $221,002 in 1886, or an increase of $46,257. The net earnings were $207,015, as compared with $162,328, showing an increase of $44,687. A quarterly dividend of 2½ per cent has been declared.

SUBMARINE TELEGRAPH COMPANY.—The accounts for the half-year ended December 31, 1887, show a balance which enables the directors, after adding 15 per cent. of the gross receipts to the reserve fund, to recommend a dividend at the rate of 15½ per cent. per annum, the same as a year ago.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended January 13 were £2,875, and for the week ended January 20, £1,722, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited).

It is stated that the business of Messrs. Willans and Robinson, of Thames Ditton, Surrey, engineers, has been transferred to a limited company of the same name, with a capital of £200,000 in 4,000 shares of £50 each. The first issue of 1,200 shares has been subscribed by the partners and their friends, and no shares are offered to the public.

We are requested to state that Messrs. Appleton, Burbey and Williamson will shortly commence business as electrical engineers and contractors at Balmoral-buildings, Queen Victoria-street, E.C.

The partnership between Messrs. S. Brierly and W. Banks, of 32, Corporation-street, Bolton, has been dissolved, but the business is now carried on at the same address, under the title of The Bolton Science Depot, with Mr. Banks as manager.

F. GEERE HOWARD,

Electrical Engineer and Contractor for Wire Running of Every Description.

MANUFACTURER OF WOOD CASINGS

FOR ELECTRIC LIGHT CABLES AND WIRES OF ALL SIZES:

Plain or Moulded, in every description of Wood.

CLEATS, SWITCH BOARDS, SWITCHES, CUT OUTS, &c.,

And every description of Woodwork for Electricians.

Price Lists and Quotations upon Application.

CLEVELAND WORKS, CLEVELAND ST.,

LONDON, W.

CARBONS.

THE BARNSLEY CARBON CO.,

Manufacturers of

PURE CARBON POINTS, TUBES, FILTERS, CELLS, AND BATTERY PLATES

Of every description.

WORKS: BARNSLEY.

London Agency and Stores: THE GLOBE ELECTRICAL & ENGINEERING CO., 7, Carteret-street, Broadway, Westminster.

TELEGRAPHIC ADDRESS: "CARBON, BARNSLEY."

FREDK. LACK and SON,

90, STRAND,

CONTRACTORS FOR SHIPS' LINEN & BEDDING.

ALSO FOR

Household and Cabin Furniture, Carpets, Linoleum, China, Cutlery, and Plate for Export.

TELEGRAPH STATIONS FURNISHED THROUGHOUT

Contractors to the Telegraph Construction and Maintenance Company, Eastern, Eastern Extension, Brazilian, and African Direct Telegraph Companies.

PATENTS FOR INVENTIONS,

REGISTRATION of TRADE MARKS and DESIGNS in all countries.

SEARCHES made *re* novelty, and opinions given on all matters connected with above.

Full particulars on application to

WESTERN ELECTRIC COMPANY.

MANUFACTURERS OF

Magneto Bells, Switchboards, Insulated Wires, Anti-Induction Cables, and all requirements for Telephone Exchanges.

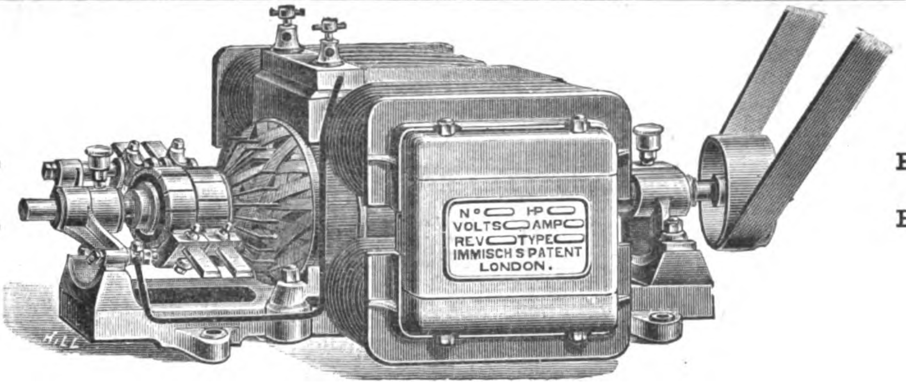
Dynamos, Arc Lamps, and all apparatus for ELECTRIC LIGHTING.

Hotel and House Annunciators of improved design, and other ELECTRIC BELL APPARATUS.

79, COLEMAN STREET, LONDON,

CHICAGO, NEW YORK and ANTWERP.

Highest Award for Electric Motors at the International Inventions Exhibition, London, 1885



Highest Award for Electric Motors at the International Exhibition, Antwerp, 1885.

Telegraphic Address: "IMMISCH," London.

IMMISCH,

Telephone No 7585.

ELECTRIC MOTORS & DYNAMOS,

Malden Works, Prince of Wales' Rd., London, N.W.

MOTORS FOR LOCOMOTIVES, TRAMCARS, LAUNCHES, FANS, LIFTS, CRANES, &c., WOUND TO ANY TENSION.

Great attention given to fitting up Factories with Electric Power, and quotations given for Electrical Transmission of Power for all kinds of Industrial purposes.

DYNAMOS OF ALL SIZES AND DESCRIPTIONS.

For Pumping, Hauling, and Winding, In Mines, Collieries, and Ironworks.

MACHINES MADE FOR SPECIALLY SLOW SPEED. FULL PARTICULARS AND PRICE LISTS ON APPLICATION.

EMPIRE CARBONS.

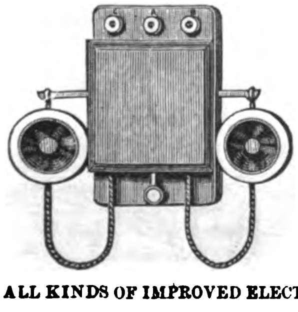
11mm. Solid 1½d. per foot, 11mm. Cored 2d. per foot.

OTHER SIZES AT PROPORTIONAL RATES.

Belfast Electric Appliances Co., Limited,

Telegrams, "Empire," Belfast. **BELFAST, IRELAND.** Telegrams, "Empire," Belfast.

IMPROVED PATENT ELECTRIC TELEPHONES.



SPECIAL FEATURES:

1.—Loud and Distinct Articulation.
2.—The Construction, Fixing and Maintenance as simple as an ordinary electric bell.
3.—Reasonable in price.
4.—Suitable for all purposes.

For all particulars apply to

W. Blenheim & Co.,

Englefield Green, Egham.

ALL KINDS OF IMPROVED ELECTRIC BELLS & APPARATUS MANUFACTURED.

A formal guarantee against any claims made for alleged infringements will be given to any purchaser requiring the same.

SINGLE WIRE MULTIPLE TELEPHONE SIGNAL COMPANY, LIMITED.

By this Company's Patents Ten or any less number of Telephones or Telegraph Instruments can be used upon a single wire.

The Company also possesses Patents for STREET FIRE ALARMS on both Separate and Single Wire Systems.

The Metropolitan Fire Brigade, Her Majesty's Post Office, the Lancashire and Cheshire Telephone Company, the Eastern Telegraph Company, and others use this Company's System.

PARTICULARS ON APPLICATION TO THE

Secretary, 11, Old Broad Street, London, E C.

THE INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY, LIMITED.

Offices and Warehouses: 106 and 100, CANNON STREET, LONDON, E.C.
Works: Silvertown, London, E. and Persan-Beaumont, France.

TELEGRAPH ENGINEERS AND MANUFACTURERS OF

CABLES.—Submarine, Subterranean and Aërial.

WIRE.—Insulated with India Rubber and Gutta Percha, to all gauges.

INSTRUMENTS.—"Morse" Inkers, Single Needle, Wheatstone's Alphabetical, Preece's and Walker's Systems of Semaphore "Block" Instruments, Bells, Resistance Coils, Sir W. Thomson's and other Galvanometers, Condensers, Testing Instruments, Indicators for domestic use, Electric Bell Materials, &c.

BATTERIES.—**Sole Manufacturers for Great Britain, Ireland, and the Colonies of the celebrated Silvertown Improved Leclanche and Poggendorf Bichromate Batteries** All other kinds of Batteries also manufactured. Ebonite Cells Carbon Plates, &c.

The Leclanché is the best Medical Battery.

INSULATORS.—Ebonite, Porcelain, Brownware, &c.

ELECTRIC LIGHTING.—Electric Lamps, Dynamo-Electric Machines, and Metallised and Ordinary Carbon Rods for Electric Lighting.

Manufacturers of the most Improved Apparatus for RAILWAY BLOCK-SIGNALLING.

SEMAPHORE REPEATERS, "LIGHT" INDICATORS, & WALKER'S PASSENGER-&-GUARD COMMUNICATOR.

TELEGRAPH STORES AND APPARATUS OF EVERY DESCRIPTION.

TORPEDO APPARATUS.

The Company are Patentees and Manufacturers of a Complete System of Torpedoes for Harbour and Coast Defence, and of the

SILVERTOWN PATENT FIRING BATTERY.

A Constant Battery for Mining and Blasting Purposes.

Contractors for the Manufacture and Laying of Submarine Cables of every type in any part of the world, and for the Complete Equipment of Telegraph Repairing Ships.

CONTRACTS ENTERED INTO for the SUPPLY, CONSTRUCTION, and MAINTENANCE of TELEGRAPH LINES, and ESTIMATES GIVEN for ALL KINDS of ELECTRIC HOUSE BELL WORK.

Electric Lighting for Mansions, Public Buildings, Factories, Streets, &c.

INSTALLATIONS of all Sizes Carried Out in any part of the World.

R. E. CROMPTON & CO.,

Makers of Dynamo Machines, Arc Lamps, Switches, Plain and Ornamental Fittings, Current and Potential Indicators, and all Requisites for Electric Lighting. Estimates given Free on receipt of full particulars. Address,

MANSION HOUSE BUILDINGS, LONDON, and ARC WORKS CHELMSFORD. | SECOND EDITION.—**Price List Pocket Books,** containing useful Formulæ, just published. **Price: Russia, 2s. 6d.; Cloth, 2s.; Cheap Edition, 6d., free.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 508.—Vol. XX. FRIDAY, FEBRUARY 10, 1888. Price 4d.

NOTES.

We are glad to learn that the Council of the Society of Telegraph-Engineers are taking steps to bring together members of the electrical engineering profession desirous of taking part in the Paris Exhibition of next year. A preliminary meeting is announced for Monday next, 3 p.m., at the Society's office.

Mr. Kapp's paper read last night before the Society of Telegraph-Engineers and Electricians contains the first serious attempt to deal with the construction of transformers upon a thoroughly scientific basis. As such it will certainly take classic rank, as the author's paper on the "Pre-determination of Dynamo Characteristics" has already done. Although the subject is treated in the lucid and unpretentious style which is characteristic of the author, yet the paper is one which will take a good deal of careful studying before being thoroughly mastered. We should, nevertheless, strongly recommend everyone who is anxious to keep pace with the modern developments of electrical engineering to make it a point to understand, at least, the general method of treatment adopted, and particularly the passages relating to the magnetic density. Some of the conclusions arrived at will surprise most people, particularly the establishment of the slight theoretical inferiority of the Zipernowski type—or "shell type," as Mr. Kapp proposes to term it.

The enormous stride which has been made in electrical engineering during the last five years is nowhere more strikingly disclosed than in this matter of transformers. When we contrast a Gaulard-Gibbs "secondary generator" of 1883 with any of the modern types we are impressed not so much with the difference of constructive details in themselves as with the advance which has been made in the general appreciation of the principles involved. The idea of a transformer with a long straight iron core, or with no core at all, seems now almost preposterous; yet M. Gaulard was at that time practically the only man who recognised the possibilities of this simple development of Faraday's great discovery. If we are not mistaken it was a suggestion of Mr. Esson's, in 1885, which first led to the adoption, by Messrs. Gaulard and Gibbs, of a closed magnetic circuit; and even now it is scarcely two years ago that the advantage of keeping the magnetic circuit as short as possible was fully recognised.

During the recent tests which were carried out by Prof. Weber on the Oerlikon plant, employed for the transmission of power between Kriegstetten and Solothurn, great attention was paid to the loss of current by leakage, or we should rather say that great efforts were made to discover the leakage; only, as it turned out, there was no loss of current and no leakage to discover. The current at the far end of the line—a distance of eight kilometres—so far as the instruments were able to detect, was of absolutely the same value as at the starting point. Seeing that the potential in these experiments sometimes exceeded 2,000 volts, this result will be considered as remarkable as it is satisfactory. The result was attained by the use of the well known "fluid insulators" of Johnson and Phillips. In a letter to the firm —of which we have a copy—Prof. Weber lays stress on the extreme care which was taken in the measurements, and says that the result is that this method of insulation is proved to be simply *perfect*. It would be difficult to over-estimate the importance of this matter as regards the future of the long-distance transmission of energy. It has long been recognised that the employment of high potential in such a case is an absolute necessity, and it follows as a corollary that a "perfect" method of insulation is necessary. Fortunately we now know that this is already available.

Prof. Elihu Thomson's ingenious method of rendering visible the form of an alternating current wave is probably capable of improvement in detail. At present it is difficult to know how much importance should be attached to the distortion introduced by the diaphragm and the multiplying levers. If levers are employed at all, probably a better plan would be that adopted by Tyndall for rendering visible to an audience the expansion of a bar of lead with increase of temperature. This is very fully described and illustrated in "Heat, a Mode of Motion" (page 90, 6th edition). It seems, however, quite possible to obtain good results in a less complicated manner. Why not mount the mirror upon a free reed vibrating in front of the magnetic pole? In this case the compounding of two currents to note the phase difference could be very easily carried out after Lissajous's method of compounding the vibration of tuning-forks. That is to say, two electro-magnets with reeds and mirrors would be placed at right angles to one another at some little distance apart; a beam of light would be reflected from the first mirror to the second and thence to a screen. If the phases and periods were the same the ray would trace a right line on the screen,

Digitized by Google

and this would open out into an ellipse, and finally into a circle as the retardation increased (in the case of a transformer as the resistance in the secondary circuit is increased). This would clearly be better than Prof. THOMSON'S method of mounting the mirror in gimbals.

IF this method were adopted, it would become an important question to determine the proper form of reed to employ in order to get the most accurate results. Supposing that the shape of the current wave were absolutely solenoidal no doubt it would be best to tune the reed to a note having a period corresponding to the period of alternation; but Prof. ELIHU THOMSON'S results have shown already that the actual current wave may have a very irregular shape. It would, perhaps, be right to use a long reed so arranged that its vibrations were forced. But this is a question for the mathematicians. It is worth while to note that from the optical conditions it would not do to reflect the ray from the polished end of the magnet itself—or from a mirror directly fastened to it—even supposing that the magnetic elongation of the iron were much greater than it really is. In LISSAJOU'S experiments it is not the to-and-fro motion of the prongs that is brought into play, but their angular deviation. The experiment is easily made in the form which we have suggested, and we should be glad to hear from any of our readers who may think it worth while to attempt it.

WE also happen to know that an English electrician some time ago devised a method for causing an alternate current machine actually to record its own current wave in a permanent form. The apparatus has not yet, however, been made, and we do not know that we are at present at liberty to describe it. The method is of a most ingenious character, and we see no reason why it should not fully answer its purpose.

HAVING made up their minds to alter the title of their Society, the Council of TELEGRAPH-ENGINEERS AND ELECTRICIANS are acting wisely in taking prompt steps to obtain the written sanction of its members for the change. The INSTITUTION OF ELECTRICAL ENGINEERS is, all the circumstances considered, the best title that could have been chosen, and it is pretty sure to prove attractive. Whatever objections were likely to be raised among the purely telegraphic element of the Society have been fairly met in the circular just issued by its secretary. No opposition seems to be apprehended from any other quarter; and, except on sentimental grounds, probably none will be offered.

THE growth of public opinion in favour of removing the legislative restrictions on electric lighting industry could not be better illustrated than by the fact that the gas lighting journals are beginning to condemn the Act of 1882. One of them last week went so far as to recommend the extension of the present twenty-one years' limit to forty years. The conclusion being sound, we ought not to look too closely at the process of reasoning by which it is reached; but it will strike our readers as singularly inappropriate for an organ of gas lighting monopolies to allow itself to digress into the following strain when lighting by electricity is being discusssed: "Legislation," says the *Gas World*, "is progressive. The framers of laws in these days are not bound by the Acts of their predecessors. While these Acts, so far as they relate to the supply of gas, will not be abrogated, the House of Commons and the House of Lords will hesitate ere they grant authority to measures which practically confer monopolies upon recipient companies, and, to a certain extent, sacrifice the interests of the public." On this we have only to remark that, if it be true—which we deny—that the interests of the public are sacrificed whenever monopolies are conferred, "progressive" legislation of the kind which insists on buying up a terminable monopoly for an old song is not likely to spare the perpetual monopolies when their turn comes. The gas and water companies, whose immense interests some day may be threatened by legislation of that sort, ought to make common cause with us in resisting rather than condoning this "progressive" tendency.

PAPERS like that read by Mr. GEIPEL at the Institution of Mechanical Engineers on Thursday week are just what is wanted from time to time. His paper does not profess to contain any information which will be new to the electrical engineer, but rather to place before his mechanical brethren a plain matter-of-fact statement of what is now being done in everyday work by electrical means. A new thing in electricity has but very little interest to the mechanical engineer, as such. What he wants is something solid, which has been proved in hard regular work, and found a commercial success, and it is just such applications that Mr. GEIPEL deals with.

NOT so very long ago there existed among electrical engineers a more or less undefined feeling that the older branches of the engineering profession were disinclined to take them sufficiently seriously, and looked upon them rather in the light of enthusiastic amateurs. And when the force of accomplished facts rendered it impossible any longer to take this ground, it was still felt that there was a disposition to regard the electrical engineer rather as an interloper and an upsetter of established methods of procedure than a welcome ally. But from the proceedings of the Mechanical Engineers on Thursday and Friday last week, it is abundantly evident that a truer appreciation of the relation between these branches of the profession is making rapid headway. The fault—if that is not too harsh an expression for what is, after all, a perfectly natural and necessary course of development—has, undoubtedly, existed on both sides. Electricians have sometimes been inclined to talk a little extravagantly about "the coming age of electricity;" but it is now widely recognised, and will be recognised more and more, that electricity as applied to mechanics is merely an agent—an invaluable agent it may be —for the transmission of energy; and as such it will take its true position amongst the other potent agencies which science places at the disposal of the mechanical engineer. We hail the discussion on Mr. GEIPEL'S paper as a significant mark of the progress of these views, and of the more extended use by mechanical engineers of the electrical transmission of energy.

Digitized by Google

THE Financial Press is still convinced that telephone shares ought to go up, and they do go up accordingly. This is no doubt very satisfactory; but if the maintenance of these prices is to depend on the early fulfilment of the predictions on which the rise is based, perhaps the case is not so satisfactory as it looks. The *Weekly Bulletin*, like the *Financial News*, is confident the POSTMASTER-GENERAL has a Bill in his pocket for the purchase of the telephone companies. We are equally confident he has not. If possible, we are still more confident that he has no notion, as the first-named paper suggests, of handing, as an alternative, the Post Office telephone business over to the companies—at all events not if that proceeding would mean washing his hands of the telephone business altogether, royalties included. But perhaps the financial organs have forgotten all about the royalties in this relation.

Acton.—The Lighting Committee of the Acton Local Board has under consideration a proposal from the American Electric Manufacturing Company to supply electric light in that district.

The "Sunbeam" Lamp.—We understand that Messrs. Sydney F. Walker and Olliver, of Cardiff, who are the agents for the Sunbeam lamp in South Wales, have recently introduced the lamp with success in several collieries.

A Correction.—Mr. Herbert Tomlinson writes us to state that the German physicists who have recently investigated the thermo-electric properties of metals in a magnetic field are named Ettinghausen and Nernst. The *Journal de Physique* is, however, originally responsible for the spelling which we inadvertently adopted.

Royal Society of Antiquaries.—We understand that the electric lighting at the Royal Society has been extended to the premises of the Society of Antiquaries, where a total of 110 lamps is fixed. Thirty-three of Drake and Gorham's improved L31 cells in glass boxes are employed in connection with this extension, also one of their main switch-boards fitted with ring contact-switches.

Leeds.—At a meeting of the Electric Lighting Committee of the Leeds Corporation, on Thursday, it was decided to place 100 incandescent electric lamps in the mayor's rooms at the Town Hall. The arrangements for an installation to light the Fine Art Gallery, the Victoria Hall, and all other parts of the Town Hall and municipal buildings are to be considered by the committee shortly.

The Lighting of the Temple.—We understand that the Benchers of the Temple have decided to carry out a scheme for lighting the whole of their extensive domain by electricity. The Library has been so lit for some time past, and temporary installations have been carried out in the grounds and in the church on several occasions. The occupiers of chambers are also trying to get a telephone for their common use in each house.

"Annual Export Catalogue of Machinery and Hardwares." We have received from the Machinery and Hardware Company (of 147, Queen Victoria-street, E.C.) a copy of the third issue of their "Annual Export Catalogue of Machinery and Hardwares by the Principal Makers in Great Britain." The advantage of this method of advertising seems to be fully appreciated by many of the most important engineering firms; but electrical engineers are at present represented by a single firm. The catalogue is well indexed, and is printed and got up in a very creditable style.

The Lighting of Exeter.—The *Western Morning News* says:—"The lighting of the streets of Exeter by electricity is a decided success. The arc lamps are hung at a much greater height, on poles, than was the case when a few trading establishments were being illuminated some weeks ago, and the result now is that the light is not nearly so dazzling to the eyes. It is spread over a wider area, and gives perfect satisfaction. The whole of High-street is thus lit, and most of Queen-street. The gas has been put out on certain nights, and the electric light tried by itself with great advantage."

Messrs. Ransomes, Sims and Jefferies' New Catalogue.—We have received from Messrs. Ransomes, Sims and Jefferies, of Ipswich, a copy of their new Catalogue and Price List of Steam Engines. The catalogue contains drawings and particulars of several new types of engines, both portable and stationary. Our readers are aware that this firm has paid special attention to the production of engines adapted for electric lighting. On page 46 we find illustrated a special portable engine made for driving a dynamo, which is mounted on a bracket in front of the smoke-stack. This plant should prove very useful for contractors or any kind of temporary lighting.

American Carbons.—Referring to our recent remarks on this subject, the New York *Electrical Review* says:—"We have long ago learned the truth that a carbon giving fine results, say, in a Thomson-Houston lamp, behaves villanously in a Brush lamp; and in the evolution of the systems, the carbon makers of this country have done a vast amount of experimenting to establish *grades*, which should be adapted especially to the respective systems—grades which do not differ in price or quality, but do differ materially in character as to hardness, temper, &c. But it by no means follows that because a particular carbon misbehaves in a given lamp it is inferior; it is simply in the wrong lamp. If some of the English plant owners will bear this in mind, they may yet bless the 'cheap American carbons.'"

Trade Conferences at Finsbury Technical College.—A series of conferences of the representatives of various trades and handicraft industries is now being held at the Finsbury Technical College. These began last autumn, with two general conferences on technical education. The third conference, which was for the cabinet-making trade, and was attended by a large and very representative audience, was held on January 14th last. The next conference, which is for bricklayers, is to be held on Wednesday, February 15th, when Mr. James Rowlands, M.P., will preside, and a paper "On the Technical Education of Bricklayers and Brickcutters" will be read by Mr. H. W. Richards. This will be succeeded on the 18th inst. by another conference of carpenters and joiners, under he presidency of Mr. W. R, Cremer, M.P.

The Telegraph Manufacturing Company's Trade Catalogue. The Telegraph Manufacturing Company, of Helsby, sends us a copy of a new catalogue of electrical apparatus which they have recently issued. This catalogue contains a very complete list of electrical apparatus (*outside* the department known as "heavy electrical engineering," but) including all kinds of wire, bare and covered, insulators of every description, iron and wood poles, and linemen's tools. In other sections we have batteries and instruments of various types, including railway and block instruments, testing apparatus, bells and annunciators, fire alarms, &c. The firm write us that they "have endeavoured to make the catalogue as complete as possible in every section, so that contractors may have in this a *vade mecum* easily carried in the pocket for estimating for telegraph, telephone, bell, and

Digitized by Google

other work." This intention has certainly been carried out thoroughly.

The Telegraph Lines between England and Germany.—A Reuter's telegram, dated Berlin, February 8, says :—"In to-day's sitting of the Budget Committee of the Reichstag, during the discussion of the proposed purchase of the telegraph cables between Borkum and Lowestoft, and Greetsiel and Valencia, Dr. Von Stephan, the Postmaster-General, declared that it was intended to make a considerable reduction in the telegraph rates between Germany and England, after the agreement on the subject had come into force, which would be on January 1 next. The charge for the grundtaxe, at present amounting to 40 pfennige, would be abolished, and the rate per word, which is at present 20 pfennige, would be reduced to 16 pfennige. The Minister added that the British Government would take over the Borkum-Lowestoft line, and establish direct communication with London and the more important towns of England. The agreement was unanimously approved by the committee."

Train Lighting by Electricity.—The Great Northern Railway Company has now four trains running from King's Cross in which, under the direction of Mr. James Radcliffe, the telegraph superintendent of the line, a very efficient electrical plant has been fitted, and a fifth installation is in preparation for an express train to Edinburgh. A dynamo and set of accumulators are placed in the van under charge of the guard. The machine is a Brush, shunt wound, giving from 45 to 90 amperes of current, according to the speed at which the train travels. This is driven from the axle of the train wheels, multiplication of speed being obtained by means of counter-shafting. The direction of rotation of the dynamo is regulated by an arrangement designed by Mr. Radcliffe, by which the dynamo is always driven in one direction, whichever way the train may be running. The accumulators are connected with and disconnected from the dynamo by means of an automatic switch, also designed by Mr. Radcliffe.

Bournemouth.—A meeting of postal and telegraph officials was held at the Waverley Hotel, Bournemouth, on Tuesday night, Mr. F. A. K. Haunsell, A.S.T.E., in the chair, Mr. W. H. Childs vice-chair. The Postmaster (Mr. Dunn) was highly eulogised by both branches. Mr. Lynd, the editor of the *Telegraphist*, proposed the "Engineering Department of the Postal Telegraphs," coupling with it the names of Messrs. Graves, Preece, and Kempe. After giving a brief sketch of the early days of telegraphy, Mr. Lynd said that the labours of such men as he had named had made telegraphy one of the most perfect popular institutions in the world. The number of messages dealt with at the Bournemouth office last year amounted to two hundred thousand, showing an increase of twenty-one thousand on the previous year. A telegram was received from the Secretary of the Postal Telegraph Clerks' Association during the evening, urging the staff at Bournemouth to join in the struggle for their modest demands.

Lighting of a Yacht.—The steam yacht "Victoria," which sailed from Gravesend on the 4th inst. for a cruise of three months in the Mediterranean, has just been fitted with a new electric light plant, by Messrs. Browett, Lindley and Co., of Manchester. The plant consists of 150 incandescent lamps and an F 2 Victoria Brush dynamo, driven direct at 200 revolutions by a new type of vertical tandem compound engine, recently brought out by the above firm. The installation of the generating plant presented some difficulties, as the whole had to be carried on a wrought-iron platform, erected for the purpose in a corner of the main engine room, and level with the top of the cylinders. The whole plant is compact and entirely self-contained, and the engine is constructed to work either as a high-pressure engine, with 50lb. steam from the donkey boilers, and exhausting into the air, for use when in port, or to work compound with steam from the main boilers, which carry 80lb. pressure, and exhausting into the main condensers.

The Lighting of the Bute Docks, Cardiff.—We reproduced last week a paragraph from a local paper which stated that a Brush plant was being installed for the lighting of the Bute Docks, at Cardiff. We have since learnt that this is erroneous, the work having been placed in the hands of Messrs. Crompton and Co. The plant consists of three Crompton machines, each capable of supplying current for 11 DD lamps of 3,000 candle-power each. Two of these machines will be in regular use, the third being kept as a stand-by. The 22 lamps now fixed are arranged on two circuits and mounted on poles 30ft. in height. Eleven are fitted with the shadowless gear which has been so successful at Tilbury and elsewhere. By means of this arrangement no deep shadows are thrown, obstructing the light where most needed in the unloading of ships, &c., and thus great advantage is derived from their use. Most of the wires are run overhead, but in crossing locks it has been necessary to encase the cable in strong sheathing and lay it across the bottom. Divers have been at this work for some time and it is now nearly completed. The switch-board is on the most improved principle, and provides for a future extension by the addition of two more circuits, making forty-four lights in all. Instruments have been attached to the switch-board for measuring and testing. The whole work is being carried out under the supervision of Mr. W. H. Massey, who is acting as the consulting engineer to the Dock Company.

The Organ at St. Paul's.—In its interesting account of the organ loft of our metropolitan cathedral, the *Daily News* makes mention of some of the uses to which electricity is applied in the conduct of the musical service. "A 7 o'clock an electric signal flashed across the cathedral from the Dean's vestry intimates that service time has arrived. Electricity plays an important part here. Already a signal has gone down to the engine room in the crypt, where an Otto silent gas engine has been started, and the swelling bellows as it raises its huge back has automatically telegraphed back 'wind on.' It has begun to blow a small hurricane through two trunk pipes leading out of 'Willis's patent cylindrical feeders.' These feeders are four cylinders, each provided with a double set of valves; two cylinders supplying a high-pressure reservoir and two low pressure. 'Wind on' has been signalled up from the engine room, and now is heard the 'whir-r-r' from the Dean's vestry to the minor canons and the choir. If the organist is not on the alert another subdued racket will be immediately set up on an electric apparatus just over his head. After the overture, if the organist has anything to say to his choir down in the stalls below, he can communicate by telegraphic wire and speaking tube. There is another apparatus here also. On great days, when an orchestra of 50 performers and a special choir of more than 300 take part in the service, an electric communication is maintained between the left foot of the conductor down in the body of the church and a movable arm which beats time close to the music book of the player."

Evening Lectures by Prof. Perry on the Design and Manufacture of Dynamos.—We have pleasure in announcing that a special course of four lectures on the mechanical engineering involved in the design and manufacture of dynamo machines and motors will be delivered at the Finsbury Technical College, Leonard-street, City-road, E.C., by Prof. John Perry,

Digitized by Google

M.E., D.Sc., F.R.S., once a fortnight on Thursdays, at 7 p.m., commencing Feb. 16th, together with drawing office work on the same subject on the alternate Thursday evenings, from 6 to 9 p.m. The following is the syllabus:—1. Feb. 16th. Continuous current dynamos and motors in use described. Electric and magnetic rules which are now adopted, as to sizes of iron and the winding. The iron and other materials used. Where the mechanical engineer's usual methods of working must be modified. Journals. —2. March 1st. Simplicity of design. The usual causes of a breakdown. Use of machine tools. General questions of strength of parts. Armatures. The division of metal. Insulation and winding of wire, &c., on the field-magnet and armature. Lasting power and strength of joints.—3. March 15th. Forces to which the wound wire is subjected. Influence of these on design of armature. The driving of dynamos direct and by gearing. Driving from motors. Commutators and brushes, their design, insulation, strength, wear and manufacture. The electric transmission of power.—4. April 19th. Alternating current machines in use. Electric and magnetic rules. Design and manufacture in the past and probably in the future as compared with that of continuous-current machines. The past and probable future of dynamos. On the alternate Thursdays drawing office work is undertaken. The fee for this course, including drawing office work, is 6s., and apprentices are admitted at half fees.

The Electric Lighting Bill.—In *The Times* of Feb. 3 the following letter from Lord Thurlow appeared:—"The public are under a great obligation to your well-known correspondent Major Flood Page, whose letter you printed yesterday, for his very clear and powerful advocacy of the strong claims of electric lighting on the immediate attention of Parliament. As he has referred to my Bill, which passed the House of Lords last year, and expresses in very kind terms the hope that I may re-introduce it this year, I beg to say that it is my firm intention to lay it again on the table of the House of Lords so soon as Parliament re-assembles. At the same time, I entirely concur with Major Flood Page in hoping that Government may see fit to to deal with the question this Session, and enable me to withdraw my Bill and give my hearty support to their measure. The only point on which a difference of opinion practically exists in Parliament is on Clause 27 of the Act of 1882, which governs the compulsory purchase of electric lighting undertakings by local authorities after 42 years (42 years being now generally conceded in place of the original 21 years). The Board of Trade oppose any valuation of the 'goodwill' of the business. We, on the other hand, feel that nothing short of a fair valuation of that asset will insure the public being well served during, say, the last ten years of the life of a provisional order. If the valuation for compulsory purchase by a local authority at the expiry of 42 years is made on narrow principles, such as mere break-up value, without a due regard to maintaining the thorough efficiency of the plant, we hold that there is a serious danger of electric lighting undertakings being allowed to run down towards the expiry of their term, to the detriment of the public. It is, however, possible that sufficient, fair, and reasonable profits may be derived from the business during the period of 42 years to encourage the flow of capital into electric lighting undertakings which 21 years have failed to do; but we think it politic to give an electric lighting undertaking every encouragement to maintain its plant in the highest state of efficiency up to the expiry of its life of 42 years, and that for this purpose it is necessary 'goodwill' should be considered as an asset for valuation in the event of compulsory purchase by the local authority. If, on the other hand, it can be legally held and maintained that the valuation 'as a going concern' sufficiently covers this point and affords sufficient protection to the public, I for one would be glad to drop the obnoxious word 'goodwill.'"

The Society of Telegraph-Engineers and Electricians.—Proposed Change of Title.—The following circular has been issued to the members and associates of this society:—"Dear Sir: In their report to the annual general meeting, on the 8th December last, the Council stated that, 'in their opinion the title of the society, even as amended some few years ago, does not sufficiently indicate the full scope of the objects which should be, and which are, its aim, and they believe that "*The Institution of Electrical Engineers*" would be a much fitter title, as embracing more clearly all those branches of applied electrical science which of late years have assumed such prominence, and are becoming every day more important;' and they expressed their intention of taking the necessary steps for ascertaining the views of all classes of members upon the subject before submitting the proposed change of title in a formal manner to a special general meeting of members. I am accordingly instructed to request the favour of your communicating to me, on the accompanying form, as early as you conveniently can, your assent to or dissent from the proposal. The President and Council desire me to state, for the information of those members who were not present at the annual general meeting, that, judging from the manner in which the announcement of the proposal was then received, and from every other opportunity afforded them of eliciting an opinion on the subject, the suggested change has, so far, met with general opinion. There can be no doubt that the present title is inconveniently long, the consequence being that the society continues to be universally spoken of as 'the Telegraph Engineers,' with the natural result that it is still supposed by many to be a society occupying itself, as originally, almost exclusively with telegraphy; and it is a matter of common occurrence for electrical engineers, when invited to join the society, to reply that they fear they are not qualified, 'as they are not telegraph engineers.' Electrical telegraphy must always remain one of the most important applications of electrical science for the service of mankind; but it certainly is no longer, as it was when the society was first established, the *only* important one. Electric lighting, electric haulage, the electrical transmission of power, telephony, &c., are only some of the comparatively recent applications which are probably destined to rival the electric telegraph in importance, and it is evidently desirable not only that our society should deal, as indeed it does already deal, with these matters, but that its title should more clearly indicate that it is not confined to the consideration of any one of them alone. I am particularly desired to remind that still large section of the members who are either entirely or chiefly concerned in electric telegraphy, that theirs is distinctly but a branch—although a very important branch—of 'electrical engineering,' and that in these days, even more than formerly, a telegraph-engineer should be, and indeed must be, an electrical engineer. They need have no fear that their particular branch will occupy any less the attention of the 'Institution of Electrical Engineers' than it now does of the 'Society of Telegraph-Engineers and Electricians.' The President and Council believe that the tendency of the proposed change will be rather to raise the status of telegraph engineering in the world of applied science than to lessen in any way the recognition of its vast importance, and they trust that you will share their views.—I have the honour to be, dear Sir, yours faithfully, F. H. Webb, Secretary."

THE RISE AND PROGRESS OF TELEPHONY IN THE UNITED KINGDOM.

(*Continued from page 231.*)

At the end of our last chapter it was mentioned that although the Hunnings transmitter was ultimately decided to be an infringement of Edison's patent, held by the United Telephone Company, the judgment was in the first case against the Company on a technical point, namely, the inclusion of the phonograph, which was not in the first specification. The company applied for leave to disclaim the phonograph, and the disclaimer was granted in August, 1882, some three months after the application. This established the validity of Edison's patent, and this decision was confirmed on appeal in the following year.

During the interval, however, from May to August, 1882, Edison's transmitter remained unprotected, so that all transmitters coming under his patent which might be manufactured, or *bonâ fide* contracted for, during this time could be protected by *fiat* of the Attorney-General.

During this interval the United Telephone Company came into conflict with the Globe Telephone and Maintenance Company, which used the Hunnings transmitter and the receiver mentioned in a former chapter as going by the name of the "English Mechanic" receiver. This company had been registered at the beginning of 1882, though it did not obtain the Postmaster-General's licence until January, 1883.

The United Company had printed a notice on the cover of a pamphlet, containing a list of their subscribers, parts of which ran as follows:—

"The United Telephone Company have been advised by eminent counsel that all forms of transmitters in which carbon is used in a fine or powdered form—as, for instance, in the transmitters usually known as Moseley or Hunnings—and that all the so-called microphone transmitters, including those known as the Crossley and the Gower-Bell, are infringements of Mr. Edison's patent as amended by disclaimer." And "No form of magneto telephone, and no form of transmitter in which carbon or other equivalent substance is employed, whether known as Edison's, Moseley's, Hunnings', Crossley's, Gower's, or any other name can be manufactured, sold, supplied, or used in this country except under license from the United Telephone Company (Limited). Proceedings will be taken against persons infringing the company's patents and other rights as above set forth."

The Globe Company applied for an injunction to restrain the publication of these statements, which were stated to be in the nature of a libel on the plaintiffs' patents, and the case was decided by Mr. Justice Fry, in June.

In the course of the evidence it appeared that the solicitors of the defendant company, in reply to a complaint from the Globe Company, had given an undertaking that no more copies of the pamphlet containing the statements complained of would be issued, but as this was not complied with proceedings were taken. The defendant company could only plead in excuse that the subsequent issue of the pamphlet containing the obnoxious statements had been without their knowledge.

Relations begun in this fashion could hardly be expected to become very amicable; and as a matter of fact the contest between the established company and its not very formidable rival was carried on with the bitterest animosity on both sides. The older company used all its resources to obstruct the other and prevent it from obtaining way-leaves for its wires, and the Globe Company retaliated by trying to induce the United Company's subscribers to transfer themselves to their own newly-opened exchange by offering to take them on without charge until their current subscriptions had run out. In some cases they were successful, as they were charging lower prices than the older company. The conflict even descended to quarrels between the workmen of the rival companies upon the housetops and the tying together of wires to annoy the subscribers of the rival company, and resulted in some of the officials of the Globe Company being summoned to the Guildhall on the charge of malicious damage to property, which, however, was not sustained. In the meantime, large sums of money were being spent in litigation between the companies, until the contest was brought to an end in the year 1884 by the United Telephone Company accepting the offer of the Globe Company to buy up their exchange, with all their plant and the patents on which they relied.

The Globe Company had at this time only about a hundred subscribers to their exchange, and the United Company, on effecting the purchase, carried on the exchange, without connecting it to their own system, until the subscriptions ran out, when such of the subscribers as wished it were transferred—at their own prices, of course, not those of the Globe—to the United Telephone Company's exchange.

The latter company was now left without a rival in the field, but had still to fight its way against many obstacles, such as State restrictions, the difficulty of obtaining way-leaves for overhead wires, and above all the phlegmatic indifference to everything new which is so characteristic of us as a nation. In the spring of 1885 important additional facilities were opened to subscribers by the arrangement made with the Post Office authorities to connect the exchanges with the Central Telegraph Office in St. Martin's-le-Grand, and to enable the subscribers to receive and transmit telegrams direct through St. Martin's-le-Grand, on arranging with the company for payment of the ordinary Post Office tariff for inland and foreign messages.

(*To be continued.*)

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

ALTERNATE-CURRENT TRANSFORMERS, WITH SPECIAL REFERENCE TO THE BEST PROPORTION BETWEEN IRON AND COPPER.

BY MR. GISBERT KAPP.

At the meeting of the Society of Telegraph-Engineers and Electricians, held at the Institution of Civil Engineers, yesterday (Thursday) evening, the president (Mr. E. Graves) in the chair, the following paper was read by Mr. Gisbert Kapp:—

The principle on which all induction coils, and therefore all the different forms of alternate-current transformers, depend is that of a magnetic circuit interlacing with an electric circuit. In its simplest form this relation can be represented by two rings threaded through each other (Fig. 1), one representing the electric circuit and the other the magnetic circuit. Modern transformers have all a closed core, so as to compel, as far as possible, all the lines of the magnetic circuit to pass through the electric circuit, which consists of a primary and secondary coil; but they differ from each other in the particular manner in which the circuits are arranged, with a view to attain the following objects:—Reduction of the length of the two circuits, reduction of the weight of materials employed, ventilation, facility of manufacture and repair, efficiency of insulation, and reduction of cost of manufacture. Omitting for the present those considerations which more nearly concern the practical manufacture, we may divide transformers broadly into two classes—one in which the copper coils are spread over the surface of the iron core, enve-

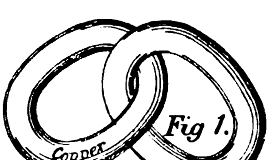

Fig 1.

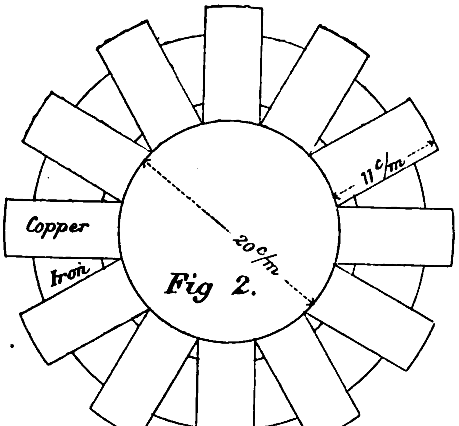
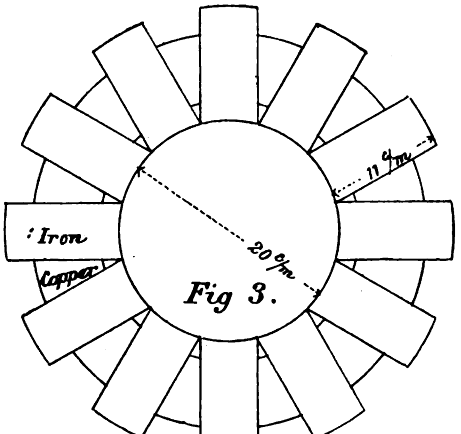
Digitized by Google

loping the latter more or less completely; and the other in which the core is spread over the surface of the copper coils forming a shell over the winding. I propose to call the former "core transformers," and the latter "shell transformers." A familiar example of the first class is the armature of an ordinary Gramme dynamo, whilst the particular type of transformer introduced by Mr. Zipernowski may serve to illustrate the second class. They are represented in the wall diagrams (Figs. 2 and 3), the copper being coloured red and the iron blue. It is evident without mathematical investigation that, whatever may be the proportion between the external and internal diameter of the ring, the electric circuit must be shorter than the magnetic circuit in the Gramme ring or core transformer, whilst the opposite must be the case in the Zipernowski ring or shell transformer. When, a few years ago, this type was introduced, it was, on account of its short magnetic circuit, generally believed to be an immense improvement upon the Gramme ring; and I have





heard it stated that with the Zipernowski outside core absolute perfection has been reached, since "every inch of copper wire contributes to produce electromotive force." I propose presently to lay before you a short investigation into the relative merits of the Gramme and Zipernowski rings, and also into the best proportion of copper to iron in either; but before entering into this subject I would submit a few theoretical considerations, so as to obtain a basis for this investigation.

Since the electromotive force developed in the secondary circuit is proportional to the coefficient of mutual induction between that and the primary circuit, and since self-induction tends to produce lag and so reduce the output of the apparatus, it is obviously advantageous, both for efficiency and output, to so arrange the coils that their coefficient of mutual induction should be a maximum for the given coefficients of self-induction in the primary and secondary circuits. According to a well-known law, the maximum value which the coefficient of mutual induction can have is equal to the square root of the product of the two coefficients of self-induction; and the necessary and sufficient condition for obtaining this maximum is that the same number of magnetic lines of force should pass through both circuits; in other words, the whole of the flow of force should take place within the core, and no free poles should be formed. This condition can easily be fulfilled by a suitable arrangement of the two circuits in close proximity, and, as a matter of fact, is fulfilled in all modern transformers. We shall therefore assume that the same flow (F) of magnetic lines of force passes through both circuits, and that the electromotive forces produced in the two circuits bear to each other the same proportion as their respective number of turns. We shall further assume that the electromotive force impressed on the terminals of the primary coil, or the current sent through it, is a simple sine function of the time—in other words, that the electromotive force developed in the armature of the dynamo is such a function. Whether the latter condition is generally fulfilled by modern machines I am unable to say; but I believe that the presence of a transformer in the circuit has the tendency to smooth down any deviations from a true sine curve should they occur in the armature, and, further, that a curve of E.M.F., of whatever shape, produced by a machine will, after filtering through two or three transformers, come out as a true sine curve. It would be of value if someone having the necessary mathematical attainments would investigate this point; but for our present purpose it is sufficient to assume that the electromotive force produced by the machine follows with fair approximation a simple sine function, and that the deviations are unimportant. This assumption has up to the present been made by all who have investigated the subject of transformers.

Let, in the following:—

n	represent the	number of complete cycles performed per second;
F	" "	flow of force in C.-G.-S. lines;
B	" "	maximum inductions (crest of wave);
τ	" "	number of turns in the coils, the indices 1 and 2 being used to distinguish the primary from the secondary coil;
E	" "	maximum electromotive forces (crest of wave) in volts, the indices 1 and 2 being used to distinguish the primary from the secondary coil;
$e = \sqrt{E}$	" "	average electromotive forces;
I	" "	maximum currents;
$i = \sqrt{I}$	" "	average currents;
L	" "	length of the magnetic circuit in centimetres;
a	" "	area of core available for the flow of lines in square centimetres;
$R = \frac{L}{a}$	" "	magnetic resistance of the core;
μ	" "	its permeability;
r	" "	the electric resistances;

then we have the following well-known relations:—

$$B = \frac{F}{a}\ ;\ F = \frac{\mu\, 4\, \pi\, \tau\, I\, 10^{-1}}{R}\ ;\ E = 2\, \pi\, n\, F\, \tau\, 10^{-3}\ ;\ \frac{E_1}{E_2} = \frac{\tau_1}{\tau_2}.$$

Calling e_{t_1} and e_{t_2} the average electromotive forces at the primary and secondary terminals respectively,

$$e_{t_1} = e_1 + r_1\, i_1\ ;\ e_{t_2} = e_2 - r_2\, i_2.$$

When a tranformer is at work we have the following phenomena:—

1. A wave of impressed primary electromotive force.
2. A wave of counter electromotive force in the primary coil, but not exactly coinciding with the impressed.
3. A wave of primary current not coinciding with either.
4. A wave of magnetisation lagging behind the primary current wave by something less than a quarter period.

Digitized by Google

5. A wave of electromotive force in the secondary coil lagging behind the magnetisation wave by a quarter period.
6. A wave of secondary current, coinciding with the former (5) in period if the external circuit contain no self-induction—a condition approximately fulfilled where the current is only used for lighting glow lamps.

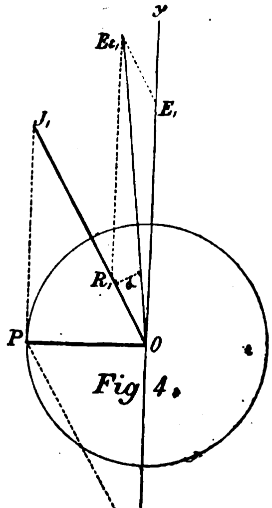
The problem now is to find what relations exist between these different waves as regards their relative positions and magnitudes. At first sight it may seem that this would prove a very difficult problem; and if an algebraic solution be attempted it is, in fact, if not very difficult, at least enormously complicated; but it is easy to treat the matter geometrically in a very simple way. As this method has already been published some time ago, it will not be necessary to demonstrate it, and I shall limit myself to a brief description, pointing out a modification of the original method by which the energy dissipated in magnetising the core can be taken into account. It will be seen from the above equations that F and E are proportional. Consequently, if we know what E.M.F. is to be put on the primary terminals of a given transformer, we also know with very close approximation what the induction and total flow of lines will be. If it were not for the slight disturbing influence of the resistance of the primary coil, we would know these data exactly. But the loss of E.M.F. by resistance can, for obvious reasons, only be trifling, and will in most cases be settled beforehand. We can therefore determine F with perfect accuracy, and from the constructive data of the core also the exciting power (τ I) which will produce this flow. It will be shown presently that it is inexpedient and uneconomical to work transformers with a high induction, and we may therefore regard the permeability to be constant for all points in the cycle. In this case τ I and F must at all times be proportional. Let, in Fig. 4, the circle represent the effective exciting power which we assume to coincide with the magnetisation, so that the projection on the vertical of the radius O P as it revolves (clockwise) round O represents the effective exciting power in ampere-turns, and, to a different scale, also the flow of force at any instant. The line representing the current in the secondary must evidently lag behind O P by a quarter cycle, and can be calculated from the formula for E_2, and from the resistance of this circuit. This gives us O I_2, the maximum exciting power due to the secondary coil alone. By erecting a vertical on O P in P, and making P I_1 = O I_2, we find the line O I_1, which represents in position and magnitude the maximum exciting power due to the primary coil alone. This gives us also the primary current, and we can now determine the loss of electromotive force due to the resistance of the primary coil. Let O R_1 represent this in direction and magnitude. The counter electromotive force in the primary must evidently be in advance by a quarter period over the magnetisation; that is to say, it must be represented by a certain length on the line O Y. Its amount can be calculated from the formula for E_1. Let O E_1 represent it to the same scale as was used for O R_1; then the parallelogram O R_1 E_{t1} E_1 gives us at once the point E_{t1} and line O E_{t1}, which represents in position and magnitude the maximum electromotive force impressed on the terminals of the primary coil, and α is the angle of lag of current behind impressed E.M.F. The work done on the primary coil is found by the well-known formula

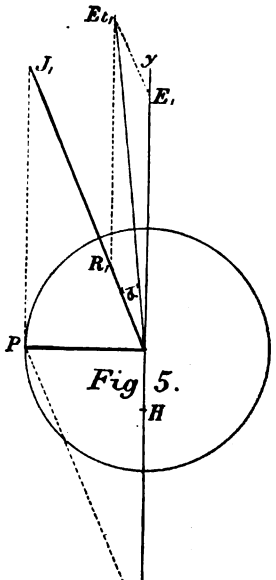
$$W_1 = \frac{I_1 E_{t1}}{2} \cos \alpha ;$$

$$W_1 = i_1 \, e_{t1} \cos \alpha .$$

That is to say, the true work is equal to the product of the apparent work, as measured by a dynamometer and voltmeter, and the cosine of the angle of lag. If the apparatus were supplied with current and at a constant and unidirected E.M.F. the apparent and the true work would be equal, and the ratio $\frac{1}{\cos \alpha}$ indicates how much larger must be the capacity of an alternate-current plant to do the same true work as a continuous-current plant. I propose, therefore, to call cos α the "plant efficiency" of the tranformer.

It was stated above that transformers should be worked at a comparatively low induction. This might seem at first sight a retrograde step, since with dynamo machines considerable gain in efficiency and output has resulted from adopting an induction up to 20,000 and more; but by reference to Fig. 4 one of the reasons why a low induction is preferable will be at once apparent. Suppose that the line O P represents the limit to which the induction may be pushed without diminishing the permeability; then, if the same transformer be worked at double the electromotive force, we would require an exciting power not only twice, but many times, as great as previously. This would bring the point P considerably to the left without increasing the length of line P I_1. It would also increase the length of the line O I_1—that is, the primary current—and therefore the heat generated in the primary coil, whilst the angle of lag would become greater and the plant efficiency smaller. Similar results would follow from an increase in the magnetic resistance of the core, or from the omission of a core altogether. An early type of transformer made by Messrs. Gaulard and Gibbs had no iron core, and therefore no well-defined magnetic circuit; but as the primary spirals alternated with the secondary spirals our previous assumption regarding the coefficient of mutual induction remains valid, and the above formulæ and graphic method could be applied to this apparatus if we knew what value to assume for the resistance of the magnetic-field. This, however, we do not know; but the case is of no importance at present, as transformers without iron cores have become obsolete. I only mention this early apparatus because the experimental investigations of Dr. Hopkinson and Prof. Ferraris* have proved that there is a considerable difference between the apparent and the true work; that is to say, the point P must have been a considerable distance to the left, making the plant efficiency small. In modern transformers the point P lies so close to O that the plant efficiency may reach as high as 99 per cent., so that the difference between real and apparent work supplied to the apparatus when giving full output becomes trifling; and for a practical determination of efficiency the readings of measuring instruments on the primary and secondary circuit may be used, with only such corrections as may be applied from the diagram.





A high plant efficiency is, however, not the only reason why transformers should be worked at a low induction. A far more important reason is the heating which takes place in the iron of the core if this be carried rapidly through cycles of intense magnetisation. This heating is not due to eddy currents (although these currents in a badly designed core would produce the

* "Ricerche Theoriche e Sperimentali sul Generatore Secondario Gaulard e Gibbs," by Galileo Ferraris. Turin, 1885.

Digitized by Google

same effect), but seems to be the result of what may be termed dissipation of energy by molecular friction or hysteresis. The energy dissipated per cycle per cubic centimetre increases in more than simple ratio with the induction, and it seems also to increase as the periodic time decreases. As yet very few experiments have been made to determine the hysteresis for different samples of iron, the most important data published being those given by Prof. Ewing and Dr. Hopkinson in the *Philosophical Transactions*, Part II., 1885. Prof. Ewing distinguishes between static hysteresis (slow period) and viscous hysteresis (quick period), but the experimental data refer only to the former. According to Dr. Hopkinson, the energy required to carry one cubic centimetre of annealed wrought iron through a complete cycle of induction equal to 18,251 lines is 13,356 ergs., and for hardened tungsten steel with an induction of 14,480 lines the energy reaches 216,864 ergs. Prof. Ewing found that with very soft annealed wrought iron and $B = 13,190$ the energy dissipated by hysteresis was 9,300 ergs. He also tested annealed iron wire by carrying it through lower cycles; and, as the results are of very great importance in the construction of transformers they are given herewith:—

Induction.	Energy.
1,974	410
3,830	1,160
5,950	2,190
7,180	2,940
8,790	3,990
10,590	5,560
11,480	6,160
11,960	6,590
13,700	8,690
15,560	10,040

These figures refer to static hysteresis. As regards viscous hysteresis, no experiments have been made; but in the case of $B = 8,500$ and $n = 80$ Prof. Ewing estimates the energy dissipated per cycle at 5,000 ergs., or 32 per cent. above that of static hysteresis. When applying the figures of the table to transformers it may therefore (until further experiments have been made) be advisable to add from 30 to 40 per cent. to the energy there given. Thus, if an induction of 18,000 be adopted, the energy dissipated would amount to 18,000 ergs. per cubic centimetre per cycle; and with 80 cycles per second this corresponds to ·144 watt per cubic centimetre of core. It would evidently be extremely difficult, if not altogether impossible, to provide cooling surface enough for this rapid generation of heat, and hence it is necessary to work at a lower induction, the exact amount to be determined for each transformer by the cooling surface of the core and coils, and by the heat generated in the coils themselves. So far, then, theory points to the necessity of low induction. As regards practice, I believe the makers of transformers have already found out that it does not pay to press the iron magnetically too hard. My own experience was at least in this direction. In the first transformer which I designed jointly with Mr. W. H. Snell, and which is on the table, we worked at an induction of 20,000, and there were produced two very undesirable results. In the first place, the core heated to such a degree that continuous work was out of the question; and, in the second place, the apparatus emitted a most unmusical sound, and it was evident that on this account alone it was not fit for practical use. The sound may have been partly due to the employment of wood for the framework, but we believed that the high induction was principally the cause, and by dropping the E.M.F. so as to get an induction of 15,000 we found that these evils were lessened. We then constructed another transformer, in which the induction was reduced to 10,000. This transformer is also on the table. In it the sound was suppressed, but the temperature still rose by about 30deg. C. when continuously at work. We have, therefore, in a later design adopted a still lower induction. Although it is possible to reduce in this manner the amount of energy dissipated in the core, this waste cannot be entirely prevented, and must therefore be taken into account when determining by the aid of the diagram the working conditions of the apparatus. For this purpose it would, strictly speaking, be necessary to know, in addition to the total energy dissipated per complete cycle, also the rate of dissipation at each point of the cycle—a knowledge which we do not possess. It seems, however, reasonable to assume that the rate of dissipation of energy by hysteresis follows the same law as the rate of dissipation of energy due to eddy currents—that is to say, that it is proportional to the rate of change of induction. When the induction passes through zero the rate at which heat is generated would be a maximum, and this would gradually diminish to zero as the induction approaches its positive or negative maximum. On this assumption we can imagine eddy currents substituted for hysteresis; and in an iron core perfectly devoid of the latter property—that is, infinitely soft—the same amount of heating could be produced by imperfect subdivision, or, better still, by subdividing it perfectly, but wrapping round it a closed conductor of such a resistance that the heat generated in this conductor equals that dissipated by hysteresis in ordinary iron. For the ordinary transformer consisting of a perfectly subdivided core of iron not infinitely soft and a primary and secondary coil, we would substitute an imaginary transformer consisting of a perfectly subdivided core of iron free from hysteresis, a primary coil, a secondary coil, and a third closed coil of suitable resistance. The current in this third coil would coincide with that in the secondary coil, and its exciting power would be added to that of the secondary coil. For example, let the volume of iron affected by hysteresis in a particular transformer be 1,000 cubic centimetres, and let the energy of hysteresis be 5,000 ergs.; the total energy dissipated would, with 80 cycles per second, amount to 40 watts. If the electromotive force produced in the secondary coil be 100 volts, then our imaginary third coil would have either the same number of turns as the secondary coil and a resistance of 250 ohms, or it might have half the number of turns and a resistance of 62·5 ohms, or any other combination giving the same loss of energy. The mean value of the fictitious exciting power would in all cases be the same, namely, the number of turns in the secondary coil multiplied by ·4 ampere. Let, in Fig. 5, O H represent the maximum value of this exciting power due to hysteresis; then the total exciting power tending to demagnetise the core, and which must in a certain measure be balanced by the exciting power of the primary coil, is represented by the length of O I—being the sum of O H and HI_2, where HI_2 equals OI_2 of Fig. 4—and the point I_1 will be pushed higher up as compared with Fig. 4. The net result of this alteration is an increase in the amount of energy which must be supplied to the primary coil. It is thus possible to nclude the effect of hysteresis in the geometrical method of representing the working conditions of a transformer. I have dwelt at some length on this question, because, notwithstanding its apparently somewhat abstruse character, it is really of very great practical importance. In some transformers the heat generated in the iron core is in excess of that generated in the copper coils, even at full output. Now, where transformers are placed in parallel between high-potential mains, it is, for obvious reasons of safety, not advisable to allow customers to handle a switch on the primary circuit, and the current must therefore be on, whether lamps are being lighted from the secondary or not. When the supply is continuous, as it obvioulv must be in a general system, the cyclic changes of magnetism in the core of every transformer will be kept up day and night; and the question of heating becomes of far greater importance than is the case in dynamo machines, which, as a rule, are only worked for a certain number of hours per day.

On the basis of the foregoing we can now investigate the relative merits of the Gramme and Zipernowski rings, and the best proportion of copper to iron in each. I have selected the two original types and one modification of each as being fair representatives of the two large classes into which in the beginning of this paper I have divided all transformers. These "rings" are both equally difficult to manufacture, and contain serious practical defects; but from a purely electrical point of view they are probably as good as the majority of transformers now in the market. Their practical defects constitute for my purpose a posi-

Digitized by Google

tive advantage, because nobody will care to claim either as his special type, and I shall thus escape the somewhat invidious task of having to compare the actual transformers made by rival manufacturers. As it is obviously impossible to conduct an investigation of this kind on absolutely general lines, it was necessary to assume rings of definite dimensions. I have selected rings of circular section having an internal diameter of 20 cm., and an external diameter of 42 cm., shown in full size in the wall diagrams (Figs. 2 and 3). The mean primary potential is assumed to be 2,000 volts, and the secondary 100 volts. The copper coils in Fig. 2, and the coils forming the iron shell in Fig. 3 are supposed to touch each other on the inside, and being of equal

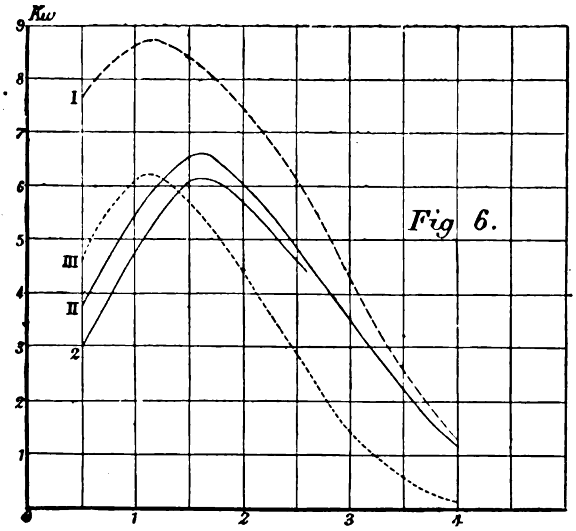


Fig 6.

depth all round, to separate on the outside, exposing part of the inner ring. In the Zipernowski transformer as actually made the inner diameter of the ring is rather smaller than shown in Fig. 3, and the shell winding covers the whole surface of the

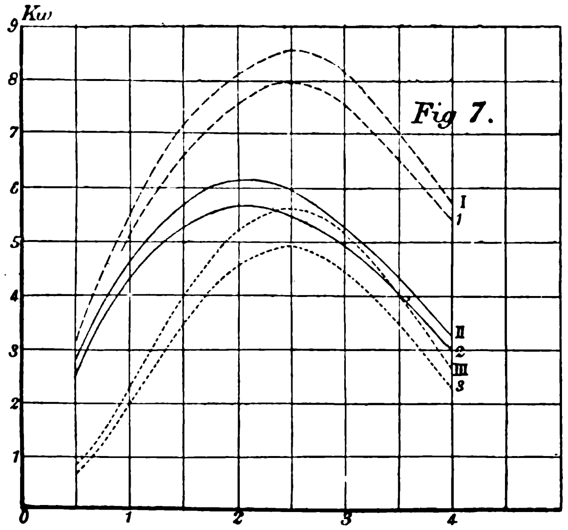

Fig 7.

conductor, being of less depth on the outside than on the inside; but the magnetic resistance is in either case so low that the difference between the assumed and actual arrangement does not materially affect the result, whilst the calculations for the former are somewhat less complicated. The total space occupied by insulation I have assumed to be 1 cm., or 2·5 mm. between the core of the Gramme ring and the primary coil, and 2·5 mm. between that and the secondary coil. The same space has been allowed for the Zipernowski ring. We can now assume different sectional diameters for the inner ring (core or coils), and depth of winding for the covering (coils or shell), so as to make up the 11cm. sectional diameter of the whole ring; and determine the output for each combination so that for continuous work the apparatus should keep moderately cool. From analogy with dynamos I estimate the total energy which may be wasted without producing overheating at 260 watts; and the output has in all cases been calculated on this basis for an induction of 8,500, a periodic time of $\frac{1}{80}$ second, and hysteresis at 5,000 ergs. As it would serve no useful purpose to burden this paper with a reproduction of the somewhat lengthy calculations, I have plotted the results in the curves II. (Figs. 6 and 7). The curves I. show the output which might be obtained if hyteresis did not exist, in which case the whole of the 260 watts would be transformed into heat within the coils. The thickness of copper winding (Fig. 6), and that of the iron shell (Fig. 7), is plotted on the horizontal, the output on the vertical. From Fig. 6 it will be seen that the maximum output with the Gramme ring is 6,400 watts with a thickness of copper winding of about 1·7 cm., leaving 6·6 cm. for the sectional diameter of the core. The cross-sectional area of the magnetic circuit is in this case about 80 per cent. of the cross-sectional area of the electric circuit, and the gross volume occupied by iron is about equal to the gross volume occupied by copper. The maximum output for the Zipernowski ring (Fig. 7) is 6,100 watts for an iron shell 2cm. thick, leaving the sectional diameter of the coils 6cm. The cross-sectional area of the magnetic circuit is in this case nearly eight times that of the electric circuit, and the gross volume occupied by iron is $1\frac{1}{4}$ times that occupied by copper. Thus, with the same external dimensions, the Zipernowski ring gives a slightly lower output than the Gramme ring; but it must be remembered that the weight of copper is also slightly smaller. I have made the same calculations for oblong rings, as shown in Fig. 8. Imagine the

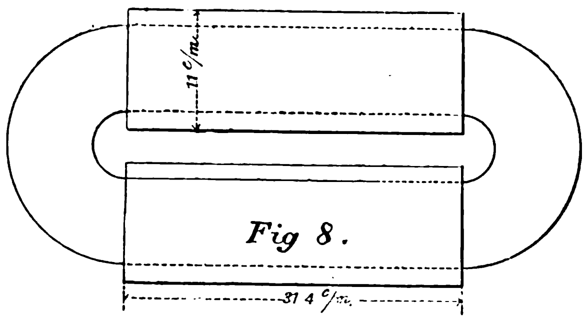

Fig 8.

Gramme ring cut in halves, these straightened and laid side by side, and the two cores joined by semi-circular pieces at the ends. The copper coils will in this process not be altered, but the length of the magnetic circuit and the volume of iron in the core will be increased; hence more energy will be absorbed in hysteresis, and the output will be reduced. In Fig. 6 the curve 2 represents the output for the oblong Gramme ring. By adopting the oblong shape for the Zipernowski ring we do not alter the mass of iron in the shell, but we lengthen the electric circuit, and increase the waste of energy in the coils. In this case also the curve of output 2 (Fig. 7) must lie below that of the circular type. Curve 1 (Fig. 7) shows the output of the oblong type if there were no hysteresis. In Fig. 6 this must obviously coincide with curve I. The maximum output of the oblong type is—For the Gramme ring a little over 6,000 watts; and for the Zipernowski ring 5,800 watts.

Up to the present we have only considered the output as limited by the amount of energy which may be wasted without overheating. But there is another and equally important consideration which affects the output, namely, the question of self-regulation. It is evident that in a transformer fed at a constant potential the induction is a maximum when the secondary circuit is open; for in this case the counter electromotive force of the primary is very nearly equal to the electromotive force at the terminals. At full work the two differ by the amount lost in resistance, and the induction is reduced in the same proportion. The electromotive force generated in the secondary coil is proportional to the induction, and we must deduct from it the loss in resistance in order to obtain the external electromotive force. Thus, if 1 per cent.

Digitized by Google

be lost by resistance in the secondary, and 1 per cent. by resistance in the primary, the difference of available electromotive force between open circuit and full output will be 2 per cent. For good lighting this may be considered the permissible limit of variation, and on this basis I have calculated the output of the four transformers above described. Curve III. in Fig. 6 gives the result for the circular and oblong Gramme ring. It will be seen that with a stout core the limit of output due to heating is reached sooner than that imposed by the condition of self-regulation, whilst for thin cores the reverse is the case. The best proportion of iron to copper is indicated by the intersection of curves III. and II. for the circular, and III. and 2 for the oblong transformer. In the latter case the core would have to be 7·2cm. in diameter, and the winding would have to be 1 4cm. deep. The output is 5,900 watts. For the Zipernowski ring curve III. gives the output as limited by self-regulation in the circular, and curve 3 in the oblong type. The diagram shows that the limit of output imposed by the condition of self-regulation is in all cases reached sooner than that due to heating. For the oblong transformer the maximum output is slightly below 5,000 watts, and the best proportion of iron to copper is given by the abscissæ of the highest point of curve 3. The external shell would have to be 2·4cm. thick, and the sectional diameter of the coils 5·2cm. From the above figures it appears that in the circular and in the oblong type the Gramme ring, dimensioned as shown in Figs. 2 and 8, gives more output than a Zipernowski ring of the same over all dimensions; the latter is therefore not superior to the Gramme ring, as commonly supposed, but somewhat inferior.

It might be, perhaps, objected that I have selected proportions different from those found in actual circular shell transformers, which have a much stouter ring of smaller mean diameter. More of the internal space is filled by the shell, and the central hole left is much smaller than shown in Fig. 3. The iron wire forming the shell is not put on in regular layers, but the turns cross each other in a more or less confused manner. There is no objection to such winding from an electrical point of view, as perfect insulation between the wires is of small importance. For the Gramme ring such winding would, on the other hand, be quite inadmissible; and it is on this account that I have selected a somewhat larger internal diameter of the rings, which gives room for regularly wound coils. But even if the rings are much stouter their proportion of output is not materially altered. If we imagine the ring of Fig. 3 contracted so as to reduce the central opening to 10cm. and the extreme diameter to 32cm., we obtain about the proportion of a Zipernowski transformer.

For convenience of calculation I have assumed a ring of these proportions to be changed into the oblong type, as shown in Fig. 8, but with this difference—that the external winding (coils or shell) on each side is only 15·7cm. long instead of 31·4 cm.; the diameter being 11cm., as before. Calculating the output in the same manner as before, I find that for the core transformer the maximum output as limited by heating is 3,230 watts, and is reached when the copper winding is 2cm. deep; whilst the maximum output as limited by the condition of self-regulation (within 2 per cent.) is 3,020 watts, and corresponds to coils wound 1cm. deep. The two curves cross each other as in Fig. 6, and the ordinate of the crossing point corresponds to a maximum possible output, as determined by the joint limit of heating and self-regulation, of 2,950 watts with coils wound 1·3cm. deep. In the shell transformer the limit of output due to heating is 3,030 watts when the shell is 2cm. thick, and the limit of output due to self-regulation is 1,650 watts when the shell is 2 2cm. thick. These figures show that even in stout rings, having proportions more nearly comparable with those of the Zipernowski transformer as actually constructed, the core type is better than the shell type.

This result refers, however, only to transformers having a core or a shell of circular section; and the question is whether by an alteration in the form of the shell the shell transformer could be improved. Any departure from the circular form of the shell must increase the length of the magnetic circuit, and must so far be detrimental; but if we can at the same time reduce the length of the copper coils, this disadvantage may be more than balanced by the reduction in the resistance of the circuits. As a matter of fact, the magnetic resistance of the shell is so low that even a considerable increase in the length of the magnetic circuit does not materially affect the difference of phase between the primary and secondary current. The two are almost diametrically opposed whatever may be the magnetic resistance. We can therefore adopt any shape of shell which will allow the length of the copper coils to be reduced. This is actually done in most modern transformers. The shell is rectangular, with the short side of the rectangle parallel to the plane of the coils, and thus the mean diameter of the coils is reduced. In addition to this the circular form of coils has been abandoned in several of the more modern transformers, so that the shell may fill more or less completely the interior of the coils.

In core transformers as now generally made the coils are not arranged all over the core, but are disposed in two sets, one on each limb of a single core. Each set of coils contains a primary and secondary circuit wound upon each other, or one between the other, so as to obtain perfect symmetry. Were this not so, and were one limb wound with the primary and the other with the secondary, external poles would be formed at opposite points of the core, and the output would be reduced. In a similar manner the coils in shell transformers are wound upon or in between each other, but there is generally only one set of coils and a double core. The distinctive characteristics of the two types are therefore as follows:—

Core transformers—One core and two sets of coils.

Shell transformers—Two cores and one set of coils.

The following are some of the principal modifications of each type:—

Core transformers—Gaulard and Gibbs, Lowrie-Hall.

Shell transformers—Zipernowski, Ferranti, Mordey, Wright, Kennedy, Statter, Westinghouse, Snell and Kapp, Gaulard and Gibbs.

As most of these transformers are on the table, I need not describe them at length. The original Gaulard and Gibbs transformers had an open magnetic circuit, and cores which could be more or less inserted into the coils so as to regulate the E.M.F. of the secondary—a provision obviously necessary where the transformers are coupled in series. In the apparatus shown in 1883 at the exhibition in the Aquarium, there were four distinct induction coils; and in that employed for lighting on the Metropolitan Railway in 1884 there were sixteen distinct induction coils, the circuits being formed by a compound cable consisting of a central primary wire and six secondary wires grouped round it. In 1885 was introduced a type of transformer with closed magnetic circuit, in principle identical with that shown in Fig. 8, but the two limbs further apart. In the same year Messrs. Gaulard and Gibbs introduced small shell transformers in their Tivoli installation, each transformer feeding one 50 candle-power lamp. The two circuits are formed by a compound cable coiled into a solenoid, through which is passed a bundle of iron wires; the projecting ends are then bent over to close the magnetic circuit on the outside of the solenoid, and the whole is encased in a perforated metal cylinder with wooden ends. In their latest design of transformer the coils are circular in plan and rectangular in section, and are surrounded by groups of U-shaped soft iron stampings slipped over from both sides and held together by two circular cast-iron plates with a central bolt. The primary circuit is split up into two coils, with the secondary between them.

In the Lowrie-Hall transformer there are two sets of primary and secondary coils, laid horizontally one above the other. The core is formed by thin broad sheets of soft iron insulated from each other by varnished calico, and the projecting ends of these plates are alternately bent up and down respectively so as to complete the magnetic circuit, the whole being clamped together in a horizontal cast-iron frame. The Ferranti transformer is similar in the mechanical arrangement, but, belonging to the shell type, has only one set of coils of rectangular section. The core is formed of thin iron strips of moderate

width insulated from each other, doubled over at the ends, and clamped in a cast-iron frame. Mr. Rankin Kennedy has devised various transformers of the shell type. For the general supply of alternating-currents he proposes to use a main current transformer at the generating station, in which currents from low-tension dynamos are to be converted into high-tension currents to be sent into the mains. The shell of this transformer is built up of moderately

wide but very thin strips, to form a rectangular frame of considerable depth, the strips being fastened by bolts at the corners. The core is composed of a series of strips of double width passing like a web through the middle of the opening of the rectangle, and thus subdividing it into two openings through which the winding passes. In another type, which Mr. Kennedy calls the "Piled Form of Subdivided Transformer," the iron portion consists of H stampings, in which the central web forms the core and the two down strokes of the H the shell, the coils being wound over the web. A number of these wound frames are piled upon each other, and side by side, the whole being clamped between cast-iron covers. Diagrammatically, this construction can be represented by Fig. 1 if instead of employing only two links we use a number of them formed into a chain consisting alternately of copper and iron circuits. In another form of apparatus Mr. Kennedy uses a Siemens shuttle armature overwound with a shell of iron wire. Mr. Wright's transformer may be described as a Zipernowski ring with coils of rectangular section and a shell of rectangular iron frames instead of the original iron winding. Each frame is cut across a corner, so that it may be placed over the core; and as the edges are packed close on the inside, but radiate on the outside of the ring, the frames form gills for the dissipation of heat. In Mr. Mordey's transformer the shell consists of thin rectangular iron plates with a rectangular opening, the strip cut out being laid across the frame to form the core of the coils. The ratio in the length of the sides of the rectangle must evidently be as 4 : 6, and that of the strip cut as 2 : 4, in order to obtain a uniform section throughout the magnetic circuit. The apparatus is built up by alternately slipping a frame over and a strip through the coil. The core of the Westinghouse transformer consists of rectangular frames, each with a central web connected to the frame on one side only, so that it can be bent back to slip over the coils. The whole is mounted in a cast-iron weather-proof box for outdoor use. The shell in Mr. Statter's transformer consists of E-shaped stampings slipped over the coils alternately from either side. To obtain the same area of iron throughout, the width at the bottom of the stamping is twice that of the limbs. In the transformer designed by Mr. Snell and myself the shell consists of U stampings forming a double trough into which the coils are laid. The covers of these troughs are formed from the metal removed from the interior of the stampings. The whole is held together in a cast-iron frame so arranged as to allow air to circulate through the core and round the coils.

To render transformers perfectly safe it is necessary to avoid leakage between the two coils. For this purpose Mr. Kent has devised a very simple apparatus, consisting of an insulated sheet of metal wrapped round the inner of the two coils, but not forming a closed circuit in itself. This sheet of metal, which thus separates the two coils completely, is connected to earth. Now, if the insulation of the primary coil should fail, the leak, before reaching the secondary coil, must pass through the sheet of metal, and is thus conducted to earth, causing the primary cut-out to melt, and thus cutting the faulty transformer out of circuit. Another safety appliance has been devised by Captain Cardew. Its object is to disconnect the primary circuit from the mains if any part of the secondary circuit acquires a certain potential above that of the earth, which will take place if a leak occurs between the two circuits. The apparatus consists of a cast-iron box on the bottom of which is laid, into a shallow recess, a strip of platinum foil terminating at both ends in circular discs. About one-eighth of an inch clear above one of these discs is set a metal disc with screwed stem at the back passing through the glass cover of the box, and connected by a fine fuse wire with any point of the secondary circuit. The box itself is connected to earth. The fuse wire holds back a contact spring so arranged that on breaking of the wire it will fly down to its contact and short-circuit the primary terminals of the transformer, after which its own primary fuse will melt and cut off the supply of current. If the potential between earth and the insulated disc in the box should rise above a certain limit (which can be regulated by screwing the disc up or down) the static attraction between the disc and aluminium foil lifts the latter into contact, allowing a leakage current to pass through the fuse wire of the contact spring, and thus releasing the latter. I am told by Captain Cardew that this apparatus has been tried at the Grosvenor Gallery installation, and been found to act in a perfectly reliable manner.

In the present paper I have only dealt with what may be called elementary principles in the construction of transformers.

Digitized by Google

As, however, the application of transformers is a matter of far greater importance to our profession at large, I trust you will allow me to say a few words on this subject, not with the object of imparting information, but in the hope that a discussion of real practical value may be the result. Up to the present, distribution by transformers has been made either on the single series or the single parallel system; compound parallel, the three-wire system, or any other refinement of direct supply methods, have, to my knowledge, never been attempted with transformers. The series system must fail for want of self-regulation where the lamps are to be connected in parallel and controlled independently of each other; but for very extensive and sparsely lighted districts, with the lamps supplied by each transformer in series on the Bernstein system, a series arrangement of transformers will admit of perfect self-regulation, provided the primary current be kept constant, and will, moreover, be cheaper than the parallel system. For general purposes, and especially for the dense lighting required in towns, the only practical method at present in use is to connect the primary terminals of the transformers all in parallel, and the lamps also in parallel, across the secondary circuit of each transformer. In principle this arrangement is adopted in England, America, and on the Continent; but the methods differ in these countries. Here the distribution is made by a high-tension network of mains, and the transformer of each subscriber is directly connected with the mains. In America a double network of overhead mains is employed, one for the high-tension and the other for the low-tension currents. These mains are supported generally on the same poles, to which are also fixed the transformers, and the subscriber's connection is made with the low-tension mains wherever convenient. On the Continent a network of low-tension underground mains is used for distribution in the same way as if the supply were on the direct system, and this network is fed by alternating currents at certain points where fairly large transformers are installed. The primaries are connected with the station either by overhead wires or by a special kind of cable containing two circuits insulated from each other and arranged concentrically. The cable is protected by a double lead covering and by an iron sheath formed of spirally-wound tape. Of the three methods here described our own appears to be the worst, the American slightly better, and the Continental the best. To string high-tension wires over and across our streets, allow high-tension branch leads to pass into our houses, and give every subscriber a little transformer to himself, more or less within the reach of the inmates, seems to me to be positively courting disaster. Such rough-and-ready methods may do as long as the light is not generally installed throughout a district; but once assume that every householder is using it (and it is that we are hoping for), the thousands of branch wires and transformers in the houses must constitute a very serious element of danger. In the American plan the high-tension wires are not brought into the houses, and in so far there is little danger to the inmates; but of course in the streets there is the same danger as here from the overhead wires.

Now, the Continental plan may almost be called absolutely safe. With an arrangement like Mr. Kent's dividing sheet to prevent leakage, or Captain Cardew's ingenious apparatus for detecting it and cutting off the supply, the secondary circuit can never acquire a potential sufficiently high to endanger life or property. This network can be composed of comparatively light cables, because we can feed it at frequent intervals and thus insure constancy of pressure at all places and at all hours. The transformers would be fairly large—say from 500 to 1,000 lights each—and could be installed in rooms to which no person but the authorised attendant has access; and by placing the primary feeding mains also underground accidents would be rendered almost impossible. The method of using an underground secondary distributing network has also the advantage that, should at any future time storage batteries become sufficiently improved to render distribution by continuous currents possible, the whole of the cables would be available for this purpose without any change.

[We are indebted to Messrs. Gaulard-Gibbs, Mr. Rankin Kennedy, and Messrs. Sharp and Kent, for some of the blocks used in illustration of this paper.]

MEETINGS OF SCIENTIFIC SOCIETIES.

TO-NIGHT (FRIDAY), February 10th.

ROYAL INSTITUTION.

9 p.m. Discourse on "Safety Lamps in Collieries." By Mr. W. H. PREECE, F.R.S., M.R.I.

INSTITUTION OF CIVIL ENGINEERS.

7.30 p.m. Supplemental Meeting for Students. Paper, "Arched Ribs and Voussoir Arches." By Mr. H. MEDWAY MARTIN, Wh. Sc., Stud. Inst. C.E.

PHYSICAL SOCIETY OF GLASGOW UNIVERSITY.

"Apparatus for Determining the Horizontal Component of the Earth's Magnetism." By Mr. T. GRAY, B.Sc., &c.

SOCIETY OF ARTS.

8 p.m. Indian Section. "The Work of the Afghan Frontier Commission." By Captain MANIFOLD, R A. Mr. M. MACLEAN, M.P., will preside.

"Facts regarding the Religions of India, and their Influences on the Moral Progress of the People." By Sir WILLIAM W. HUNTER, K.C.S.I., C.I.E., LL.D.

SATURDAY, February 11th.

ROYAL INSTITUTION.

3 p.m. Lecture, "Experimental Optics" (4). By Lord RAYLEIGH.

NATIONAL SMOKE ABATEMENT INSTITUTION (at the Society of Arts).

8 p.m. Lecture on "Town Smoke and House Warming." By Mr. A. E. FLETCHER, F.C.S.

MONDAY, February 13th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture III. "Yeast, its Morphology and Culture." By Mr. A. GORDON SALOMON, F.C.S., F.I.C.

TUESDAY, February 14th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read with a view to discussion, "The Economic Use of the Plane-Table in Topographical Surveying." By Mr. JOSIAH PIERCE, Jun., M.A., A.M.I.C.E.

SOCIETY OF ARTS.

8 p.m. Applied Art Section. "Principles of Design, as applied to Bookbinding." By Mr. HENRY B. WHEATLEY. Sir GEORGE BIRDWOOD, K.C.I.E., LL.D., M.D., will preside.

ROYAL INSTITUTION.

3 p.m. Lecture, "Before and After Darwin" (5). By Mr. G. J. ROMANES, M.A., &c.

ROYAL VICTORIA HALL (Waterloo Bridge-road, S.E.).

Lecture, "Earthquakes and Volcanoes." Illustrated by Dissolving Views. By Mr. EDWARD WETHERED. Chairman, Hon. and Rev. CANON PELHAM.

WEDNESDAY, February 15th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "Type-Writers and Type-Writing." By Mr. JOHN HARRISON. Sir HENRY THOMPSON, F.R.C.S., will preside.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Meeting. The following Papers will be read:—"Electrical and Meteorological Observations on the Peak of Teneriffe." By the Hon. RALPH ABERCROMBY, F.R.Met.Soc. "Rainfall of South Africa, 1842-1886." By Mr. W. B. TRIPP, M.I.C.E., F.R.Met.Soc. "Some Methods of Cloud Measurements." By M. NILS EKHOLM.

ROYAL VICTORIA HALL (Waterloo-Bridge-road, S.E.).

Meeting of Employers and Working Men to discuss the best means of obtaining Technical Education. Chairman, Captain Sir DOUGLAS GALTON, K.C.B.

THURSDAY, February 16th.

CHEMICAL SOCIETY.

8 p.m. Meeting.

SOCIETY OF TELEGRAPH-ENGINEERS.

8 p.m. Students' Meeting. Mr. W. E. HAYNE will open a Discussion on Mr. Cockburn's Paper on "Safety Fuses, &c."

ROYAL SOCIETY.

4.30 p.m. Ordinary Meeting.

ROYAL INSTITUTION.

3 p.m. Lecture, "Early Secular Choral Music" (2). By Prof. C. H. H. PARRY.

Sharp and Kent v. D'Humy.—In this case judgment was delivered yesterday for the plaintiff on all issues.

PARLIAMENT AND THE ELECTRIC LIGHT.

It is to be hoped that among the English measures pledged for the Session of Parliament which opened yesterday a not inconspicuous place may be found for the Electric Lighting Act Amendment Bill. Last year a measure of relief, which, although not wholly satisfactory, was one that all parties were agreed to accept, had been safely carried through the House of Lords and received the support of the Government, but was dropped in the Lower Chamber, apparently owing to the impossibility of carrying through any useful reform not borne upon the crest of some prevailing political wave or supported by the wires of party machinery. This year, with its promise of an English session, we may reasonably demand a fair hearing in the Commons for the Bill of Lord THURLOW, or its equivalent, which will doubtless be reintroduced in the House of Lords; and we entirely endorse the words of Major FLOOD PAGE in *The Times* of the 31st ult., when he claims on the one hand the right of the public to have the electric light, and on the other the right of the electric lighting companies to supply it. These rights the Act of 1882 practically extinguished, and to reassert them is the object of the legislation we look forward to in the present year.

Our six years' experience of it has sufficiently demonstrated the prohibitory character of the original Act and the vitality of the industry which it was intended to regulate. As a matter of fact the legislation of 1882 has regulated nothing; but, on the other hand, it has not succeeded in extinguishing the electric light, which has been steadily making progress without any legislative help or regulation whatever. In some ways this is a matter for congratulation; but from the point of view of the framers of Mr. CHAMBERLAIN'S Act the supply ought to have ceased altogether if it dispensed with the rules and conditions imposed by the Legislature. The supply has not ceased; on the contrary, it has extended far beyond what in the circumstances could have been expected, and it has grown rapidly in public esteem. In other words, the public have exerted their right to use the new illuminant, and the companies their right to supply it outside the area of parliamentary restrictions. What is now desired is that the restrictions upon its use within that area shall be removed; and we make bold to say that neither on commercial nor politico-economical grounds can the rights thus established in one direction be justly withheld in respect to the other. Of course their exercise must be subject to municipal or even imperial regulations, such as are found to work well in the case of the gas and the water supply. But it is one

Digitized by Google

thing to define conditions under which public works shall be carried out, quite another to frame them in the sole interests of the local authorities or existing competitors.

It has been recently stated that our demands have increased with every year's delay in amending the obstructive enactment. A fairer statement of the case would be that every year's experience has added fresh proofs that the Act was unworkable either in its original form or in that which the Government responsible for it afterwards agreed to recast it. So much capital was at first invested in the business, and such vast expectations were raised in respect to its capabilities, that terms were accepted, though with misgivings, that would now be rejected as utterly inadmissible. It is no reproach to the electric lighting undertakers to admit that their earlier calculations were too sanguine, and that their knowledge of the business now enables them to say that while ready to compete on equal terms with any rival in the field, they cannot hope to do so with satisfaction to the public or with profit to themselves on any such conditions as those enforced by the original Act, or suggested later on for their mitigation. To extend the period of concession, it was soon perceived, would not touch the main objection to its ultimate provision—namely, the compulsory purchase of the stock and plant at a valuation, the business, as a business, counting as of no value at all. So long as this extraordinary and unprecedented condition remains part of the law of the land as affecting this particular industry, so long will the parties pecuniarily interested in it increase their demands for a prolongation of the period of concession in order to cover, if possible, the loss by virtual confiscation when the concession expires. The legislation of 1882 was, in fact, a socialistic experiment which, in vulgar terms, might be called a try on. It has signally failed; and in the interests of sound economics, as well as in those of the electric lighting industry, the British public may be thankful that this ingenious essay in social plunder has been thoroughly discredited.

The two main alterations embodied in the amendments approved by the House of Lords last year were the extension of the concession period from twenty-one to forty-two years, and the substitution of compensation for confiscation. The enlargement of the period is a valuable improvement, giving greater stability to the business and a fairer prospect of adequate remuneration for the risks involved. As some of the leading companies are ready to accept this concession, we need offer no objections to their policy, supposing they are quite sure no better terms can be obtained. But obviously the Bill of Lord RAYLEIGH in 1886, placing the electric lighting business on exactly the same footing as that of water and gas, would be preferable. It seems to us that there is no need to define the period; and in the interests of the public, Parliament ought not to restrict its own future action in that hard and fast way. Parliament could at any time enact the compulsory purchase of any gas or water company in the kingdom, notwithstanding their nominal monopoly in perpetuity. So long as the terms of purchase are not prescribed in the first instance unfavourably for the expiry of their business, the companies need not trouble themselves about the date when their existence will terminate. It would be far better to define nothing whatever in respect to time or terms. It was the precise definition of both that constituted the new and mischievous departure of Mr. CHAMBERLAIN'S Act. If, however, in these days we must yield to the heretical tendencies of social legislation, the terms of purchase, if defined at all, must be our chief object of consideration. On this point electrical engineers should bring all their united energy and influence to bear, for on this will depend their power of raising capital to work under the amended Act. That they did not combine together in respect to the original Act was made pretty evident in Mr. T. H. BLAKESLEY'S able pamphlet, "Electricity at the Board of Trade," published soon after the Board had framed those regulations which, as every electrical engineer now knows perfectly well, were simply incapable of practical realisation. These gentlemen only combined to make identical requisitions for provisional orders which were never taken up, and which, perhaps, they never seriously intended to take up. Let them now unite for the more legitimate object of influencing the Legislature, and obtaining that relief to which the importance of their business and the wants of the public entitle them. Unless something unforeseen should occur, there is reasonable ground for hope that a satisfactory amendment of the Electric Lighting Act may be carried this Session if the parties most concerned are agreed as to what they urgently need and will cheerfully accept.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

CHAPTER VII.—*Simple Tests with Indicators (continued).*

(Continued from page 322.)

77. The manner of working out a simple insulation test with an indicator as above described will now be shown. It will be noticed that no mention has been made of the testing of the insulation resistance of a submarine cable by this means, since it requires a more delicate instrument to do this, not only on account of the far higher insulation resistances of cables for the same length, but also because it is necessary to watch their behaviour during a test, and therefore a delicately suspended needle which will detect minute changes is necessary. In addition to this there is a condenser-like action causing the resistance to increase during the connection of the testing battery. This effect observed in cables when one end is "free" and the other connected to a battery is known as "electrification," and will be considered further when the more delicate instruments applicable to cable tests have been examined. For the present test, however, we are considering overhead lines, such as bare telegraph wires with an insulation ranging from, say, half a megohm to 10 megohms per mile, according to the state of the weather, and long overhead covered main wires supplying lighting currents from a central station where an insulation of about one to two hundred thousand ohms per mile may be expected.

Suppose now, that a sensitive horizontal indicator is connected up to one end of an overhead line 10 miles long, and that the other end of the line has been carefully "freed." Before connecting up the battery the indicator must be "set" by turning it round till the pointer is at 0°; the needle is then parallel to the plane of the coils. While doing this everything in the immediate neighbourhood of the instrument likely to be magnetised and moved about must be removed altogether and placed at a distance where it cannot affect the needle, otherwise very discordant results may be obtained. Especially must pockets be ransacked of everything magnetised, as these approach very near the instrument when bending over to read the deflections. Anyone who is much in the company of dynamo machines has everything about him in the shape of steel magnetised. Some little time ago a letter appeared in one of the electrical papers from an electrician who had wasted a lot of time trying to find out what affected the needle of his testing instrument, and having discovered the cause of these erratic movements kindly gave others the necessary warning. After ransacking pockets and removing everything he considered magnetic, together with his umbrella, to a distance, he at last found that his hat contained something magnetic and was doing the mischief. This he did not discover by pulling the hat to pieces, but by politely taking it off before the instrument and moving it about near the needle, when the effect was evident. The circuit should now be com-

Digitized by Google

pleted by connecting the remaining terminal of the instrument to a battery of, say, ten cells, and the other pole of this battery to earth, as shown in section 76, Fig. 36. If the deflection is larger than 45deg. the battery power should be reduced until it approaches that angle, but it is more probable that considerably less than this will be observed. The current now passing through the instrument is due to leakage from the line to earth, generally a uniform leakage at each post or support, and the exact resistance which this represents can be calculated by observing what deflection is produced by the same battery through the instrument and a *known* resistance. The calibration of indicators or the comparison between their deflections and the currents producing those deflections not having yet been explained, it is not supposed that we know whether the instrument reads proportionally to the current or not, in which case the known resistance would be one that could be adjusted to any amount, and this would be varied until the instrument showed the same deflection as was observed when in connection with the line. We should know then that the insulation resistance of the line was equal to the known resistance through which (together with the instrument in circuit) the same battery produced the same current. The insulation resistance per mile would then be the total resistance of the whole line multiplied by the number of miles, which in this case we assumed to be ten.

78. It must, however, be pointed out that this rule for calculating the insulation resistance per mile by multiplying the total resistance by the number of miles can only be applied with accuracy to cases where the total insulation resistance of

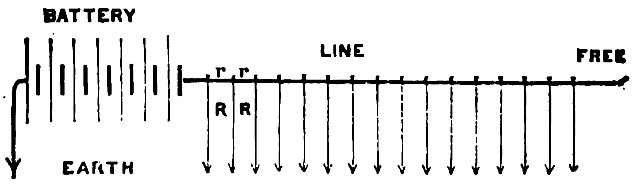

FIG. 42.

the line is very high compared to the resistance of the conducting wire itself, for when this is the case the leakage of current from the line is practically uniform; but where the conductive and insulation resistances approach each other in value the leakage of current will be greatest at the battery end of the line and become less and less gradually along the length of the line, the effect being easily understood by considering the line as made up of a very large number of equal sections, the conductor resistance of each section being r ohms, and its insulation resistance R ohms (Fig. 42). This will be precisely the same state of affairs electrically as the diagram in Fig. 43—that is, the resistances of the sections r and R are connected

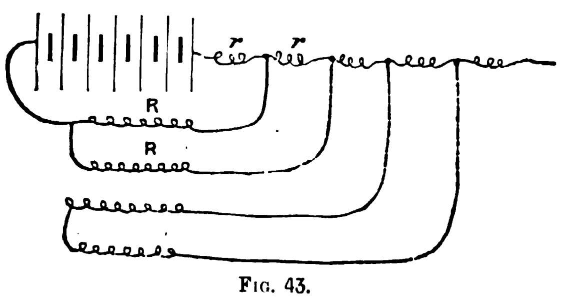

FIG. 43.

up to the battery in exactly the same way. Now it is clear that if the several resistances r r are negligibly small in comparison to the insulation resistances R R, the latter are all virtually connected direct on to the battery terminals, in which case the current through each would be the same—that is, the leakage would be uniform along the line; but if the resistances r r are so high, or R R are so low, that the former cannot relatively be neglected, then each resistance R receives less current as it is further removed from the battery, not only because it has an extra resistance r added to it each time, but because the potential difference between its ends is less each time, owing to the resistance r being added to the previous resistance R. In fact, the first section, $R+r$, is direct on the battery terminals, and therefore receives the highest potential difference, the next section, $R+r$, is connected to R of the previous section, instead of to the battery, hence it must receive less potential difference, and carry less current; and so on through all the sections. We should therefore expect to get less deflection for the same insulation resistance when the conductor resistance approached in value the former than when it was negligible. This is the case, and the insulation resistance therefore comes out too high, and necessitates a correction being applied. Mr. H. R. Kempe, in his "Handbook of Electrical Testing," has worked out in detail the mathematical process in evolving a correction for the above. This correction is applied as follows:—A test is taken of the resistance of the line when the far end is put to earth, which gives the *observed* total resistance of conductor. Now, instead of multiplying the total insulation resistance by the *actual* known length of the line in miles to derive the insulation per mile, the total resistance is multiplied by the number of miles as *calculated electrically* from the above test, the calculated mileage being the

$$\frac{\text{observed resistance of conductor}}{\text{known resistance of conductor per mile}}.$$

For instance, take 300 miles of ordinary telegraph line run with No. 8 galvanised iron wire, known to have a resistance of 14 ohms to the mile, and suppose that on testing this length of line its insulation was found to be 10,000 ohms, and that on earthing the other end and testing for conductor resistance this was found to be 3,500 ohms. Here the two resistances approach each other in value—that is, one cannot be neglected—and therefore the true insulation resistance per mile is 10,000 ohms multiplied by the *calculated mileage*, this latter being $\frac{3500}{14} = 250$ miles. This gives the true insulation per mile to be $10{,}000 \times 250 = 2{,}500{,}000$, or $2\frac{1}{2}$ megohms. If calculated by the ordinary way, the result would have been $10{,}000 \times 300 = 3$ megohms, introducing an error of 20 per cent. The insulation and conductor resistance will approach each other either when the insulation of the line is impaired or a very long length of line is tested. The writer has had occasion to apply the foregoing correction when measuring the insulation resistance of a submerged cable, 1,400 knots in length, in which the total insulation resistance of this great length approached within four or five times the resistance of the conductor. Hence the resistance of the latter was by no means negligible in comparison.

(To be continued.)

ELECTRIC WAVE AND PHASE INDICATOR FOR ALTERNATING AND UNDULATORY CURRENTS.

BY PROF. ELIHU THOMSON.

The purpose of these instruments is to enable us to study the shapes of the waves of alternating currents produced by different machines and apparatus, and also to study the relations of waves in different branches or portions of an alternating current circuit, and the amount of lag or retardation of phase visibly noted.

An iron wire core or bundle, I, (Fig. 1.) is mounted on a stand and arranged so that coils C, C, can be placed upon the core. Sometimes these coils are made with multiple or parallel windings, so that two or more sets of current waves may be caused to act upon the core I simultaneously. One of the coils or one of the windings may, when needed, be used to polarise or magnetise the core I with a definite strength of magnetism, as by a battery current or other continuous current. A diaphragm suitably mounted in front of one end of the core I and constructed of ferrotype metal follows closely the fluctuations of magnetism produced in the core by the currents in the coils. The distance of the core I from the diaphragm can be adjusted. From the middle of the diaphragm a short aluminum wire, flattened out at E so as to be very flexible at that point and connected to a very light but stiff aluminum lever, L, conveys the movements of the diaphragm to the latter. The

Digitized by Google

lever L is constructed of flat metal, and placed, as shown, so as to obtain the greatest stiffness with the least weight.

The fulcrum at F is composed of a flattened place in the metal wire, so that it has no lost motion. The connection of the long arm of the lever G has also a flattened place in the wire, and a delicate pivot, H, connects and conveys the movement of the lever L to the small circular mirror M, mounted on a transverse axis and held down against the pivots so as to avoid lost motion by a spring, S, attached to the middle of the back of the mirror, and pulling on the same. The pivotal point H is put a little to one side of the axis on which the mirror swings.

Now, it will be evident by this construction that the slightest movement of the diaphragm D will be followed by a much magnified movement of the mirror M, which mirror, receiving a ray of light, will, as it changes its position, cause such ray to swing over a considerable space on a screen at a distance of 18 or 20 inches away. The beam of light is obtained from a small illuminated pinhole reflected and focussed upon the screen, placed in front of the mirror at, say, a foot or 18 inches therefrom; any movement of the mirror will therefore cause this small round spot to travel up and down in accordance with such movement.

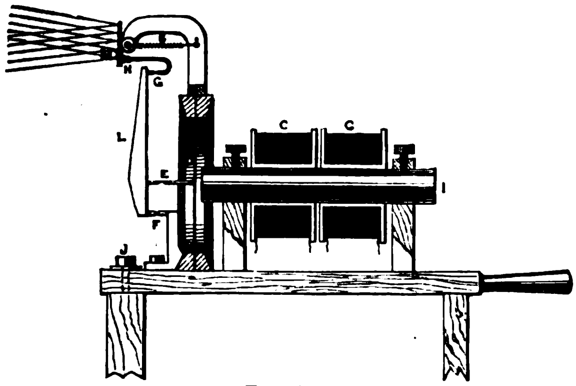

FIG. 1.

If one of the coils of such an apparatus be traversed by alternating currents and the whole apparatus be arranged to swing in a horizontal plane on a vertical axis or pivot at J just vertically under the mirror M, the spot of light will trace out a curve which will approximate closely to the shape of the current wave, much depending on the perfection with which the apparatus has been constructed for the avoidance of much inertia, by making the parts very light, and for the avoidance also of disturbing effects by having the diaphragm D traverse but a very small distance to and fro in front of the core I.

As the core I is of soft iron, unmagnetised, both the negative and positive impulses of current produce movements of the diaphragm towards the core, one by developing north magnetism, and the other by developing south magnetism at its extremity near the diaphragm. The alternating current will therefore produce a wave line like that seen in Fig. 2, in which the dotted line is the zero of current, and the curve of the waves rising therefrom is produced by currents alternately in opposite directions. If, however, a continuous current be passed through one of the coils around the core, and the strength of this current gradually increased, the shape of the wave will undergo considerable alteration, and in one stage will be represented by the wave line shown in Fig. 3, which represents the case of an alternating current passing at the same time with a continuous current in another coil, which continuous current is insufficient to so fully polarise the core I that the diaphragm D cannot be attracted by both impulses. The small wave between the larger waves is an effect produced by the overpowering of the continuous current by the stronger opposite alternating impulses, while the larger waves are due to the combined attraction of the continuous current and the alternating impulses which pass in the same direction around the core. If, however, as in Fig. 4, the polarising or continuous current be made slightly stronger, the wave takes a shape in which the opposite impulses are represented by opposite movements, or in which the upper half of the wave line represents a current in one direction and the lower half the flow of current in the other direction, except in so far as the shape may be modified by the action of the diaphragm itself. The actual appearance presented will be that shown in Fig. 5, in which the curved line is on a black ground, the apparatus, of course, being enclosed in a dark box with an opening opposite the screen for viewing the tracing of the spot of light.

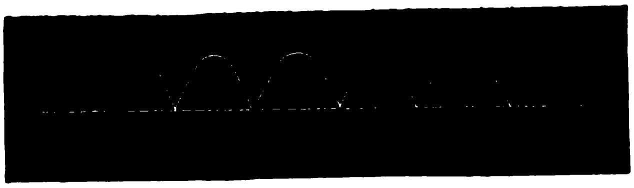

FIG. 2.

If no movement in a horizontal plane be given to the apparatus, the spot of light simply describes a vertical line whose upper and lower extremities are much brighter than the middle (Fig. 6) because of the stoppage of direction of motion which occurs in the spot of light at the upper and lower points of its swing, and of the fact that the highest velocity of tra verse exists in the middle of the swing or when the current is changing from positive to negative, or the reverse. The appearances presented in Figs. 2 to 6, inclusive, are like those which were obtained from an alternating-current machine, the

FIG. 3.

armature of which was without iron projections, such machine being one used in lighting by transformers. Fig. 7 shows a wave line such as was produced by an alternating-current dynamo having iron projections on the armature core. Here, it will be noticed, the curve is of irregular form, though regular in its irregularity. The curve indicates the sudden jumps of E.M.F. at the conclusion of each current wave, and this was undoubtedly due to the forcible pulling away of the armature projections from the field, causing, as a result, a far more rapid passage of magnetic lines across the armature conductors to the next succeeding projection; that is, the magnetism of the field on leaving one projection may be considered to quickly swing over to the succeeding projection, irrespectively of the movement of the armature, and at the same time cut all the wire between the two projections, and thus give rise to a jump or strong impulse of E.M.F.

FIG. 4.

Comparing the curves (Figs. 5 and 7) it will be seen that the armature without projections has given a more perfect wave and that the induction is much smoother, no irregularities of E.M.F. showing themselves. Fig. 8 shows the appearance presented by the spot of light with the same current as in Fig. 7, but with no lateral or horizontal movement given to the mirror. In this case, as in Fig. 6, the spot shows a vertical image or bright line, but instead of the upper and lower extremities being the only points of the line which are bright, the line shows a tendency to the formation of bright spots at other points in its length, and these correspond with those positions in the wave at which the spot of light either hesitates or changes its direction of movement. In fact, the appearance (Figs. 6 and 8) is as though the waves (Figs. 5 and

Digitized by Google

7) were composed of a wavy band of light, and were seen on end or in the plane of their propagation.

The apparatus with a single movement of the mirror (Fig. 1) is not well adapted to the study of the relations of the position of phase of two alternating currents, but by adding an additional core with its coils, and an additional diaphragm and lever, and connecting the second set so as to impart a motion to the mirror at right angles to that given by the first set, the capabilities of the apparatus are much extended. The mirror for this purpose is mounted in gimbals, and a connection made from one lever which receives its motion from one of the diaphragms to the mirror, and from the other lever and diaphragm to the surrounding ring to which the mirror is pivoted. All the moving parts are made as light as is consistent with proper rigidity.

FIG. 5.

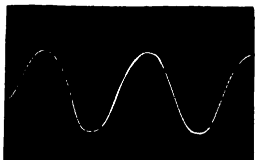

FIG. 6.

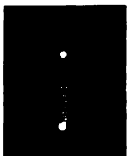

FIG. 7.

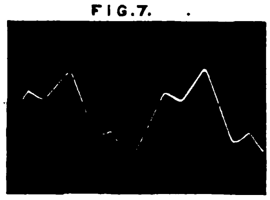

FIG. 8.

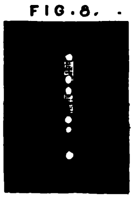

Now, if the same current or currents of exactly matched phases act to move both diaphragms and the angular deviations of the mirror be balanced or equal, the mirror will cause the spot of light to travel in a straight line intermediate to the two combined movements given by the two levers.

If, however, the phases of the alternations do not match, or one lags behind the other, the spot of light will describe an ellipse, one of whose axes will be more or less inclined from the vertical. In Fig. 9 Z is the screen, M the mirror receiving the double motion, K a source of light, and N a lens suitable to form on the screen Z an image of a small pinhole at Q. Further, if the condition be such that one of the diaphragms be affected by a current whose retardation of phase is 90deg. behind that of the other, and the currents be of equal value in moving the mirror, a figure approaching a circle will be seen on the screen, which figure would be a perfect circle were the shapes of the waves perfect.

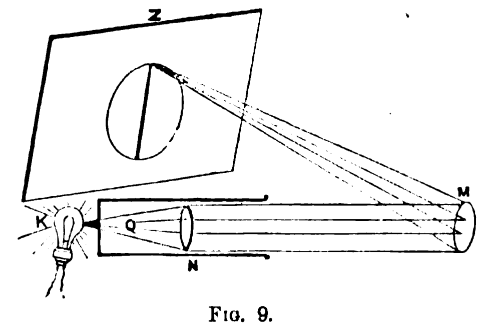

FIG. 9.

In actual trials with the apparatus it has been found that by combining the effects of alternating currents in circuits and branch circuits, a variety of figures, mostly ellipses, the relation of the length of whose axes varied greatly, and the inclination from the vertical of the axes of which also varied greatly, were produced. The changing position of the axes of the ellipses with respect to the vertical, if properly noted, gives an indication of the amount of angular lag or retardation of phase existing in one current as distinguished from the other.

It may be objected that the apparatus itself, on account of its inertia, must give rise to a retardation of the record; but it will be seen that the two diaphragms, levers, &c., being substantially the same in character and dimensions, the inertia or retardation will be practically a constant effect, and that any difference existing can be eliminated by exchanging the currents from one coil and diaphragm to the other, so as to cause them to alternately affect the diaphragms, in which case the mean effect would be taken.

It is outside of the purpose of this description to note all the uses to which this apparatus has been, and may be, applied. A few may, however, be mentioned. In Fig. 10 G represents an alternating current generator feeding a primary line, from which branches are taken off at intervals. T represents a transformer, the load in the secondary circuit of which may be varied from nothing up to full work. The coil C affecting one diaphragm is placed in the main circuit of the generator, and the coil C′ in the branch through the primary of the transformer affects the other diaphragm, the adjustments being made such that the vibratory effects of each, or the amplitude given to the wave movements of the spot of light by each, are equal. In an actual case of this kind it was found that the transformer under no load gave nearly a circle, and therefore showed that the currents passing through the primary had a lag or retardation of approximately 90deg., or one-quarter of a wave length, and this condition was departed from or modified by throwing on the load in the secondary. Space does not permit a full description of the actions, which were, however, very interesting.

Comparisons are also easily made with this apparatus between the positions of phases of the secondary currents and those of the primary currents in the transformer. By the use of a sufficiently bright light, as that of an arc lamp, and sensitive gelatine plates, the figures may of course be photographed.

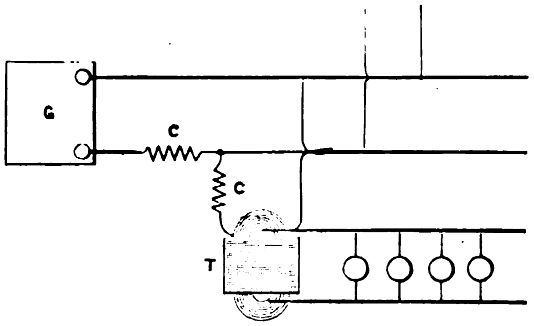

FIG. 10.

The apparatus in either of its forms, single or double, may also be used as an indicator of the extent to which synchronism takes place in two alternating-current machines or sources; or, again, it may be used to indicate the differences of shape of wave produced by such machines. In this case it is only necessary to use the apparatus of Fig. 1, employing a double-wound coil, through which the currents from the two machines pass differentially and produce equal amplitude of vibrations in the spot of light. This can be noted, and adjustment of the extent of swing of the spot on the screen be made with each current separately.

The suggestion may here be made that, having constructed as perfect a machine for generating alternating currents as possible, one in which the spacing of the waves during a revolution is exact, and the amplitudes of such waves the same throughout a revolution, and the form of the wave that which may be considered best in practice, it would be easily possible, by coupling another machine to the first, so as to rotate in perfect harmony therewith, to note the divergences of form of amplitude and position of waves in the two machines.

It will be evident that the curves obtained will only represent the true waves of current when the movement of the diaphragm is proportional, or nearly so, to the current in the coil around the core I. The current at any time will produce magnetism in the core substantially proportional to the current at any instant, which magnetism induces opposite magnetism in the diaphragm; and the pull on the diaphragm would be nearly as the square of the current at any instant when the magnetism induced is far below saturation, so-called. The magnetic pull on the diaphragm is opposed by the elastic force of the same acting as a sort of compound spring against the pull upon it.

Digitized by Google

The nature of the effects will also vary somewhat with the distance from the diaphragm at which the core I may have been placed. Whether it will be possible to adjust all variations so that the movement of the spot of light may be in exact proportion to the current whereby the true waves may be obtained is not known.

It is to be understood that, in the use of such apparatus as has been described, the effects of the resistance and self-induction of the coils C traversed by the waves of current should be so small as to have no considerable effect on the currents to insure even moderate accuracy in the indications obtained.

STANDARDISING SIR WILLIAM THOMSON'S BALANCES.

At a meeting of the Physical Society of Glasgow University held on Friday last, an interesting paper was read by Mr. Andrew W. Meikle, who described a course of experiments by which a number of Sir William Thomson's balances were independently standardised by the electrolysis of copper sulphate solutions.

Two centi-ampere balances standardised eight months ago were at that time found to be in absolute agreement when compared with each other. These two instruments have been compared from time to time since that date with a view of checking their relative constancy, and are still in absolute agreement.

Two deci-ampere balances, A and B, were also employed in the experiments. One of these was used to determine the constant of deci-ampere balance A; while the constant of deci-ampere balance B was taken from three separate electrolytic experiments which were in very close agreement, the first differing from the second by $\frac{1}{600}$ per cent., and the second from the third by $\frac{1}{80}$ per cent. These two balances, A and B, when compared together, showed a difference of $\frac{1}{105}$ per cent., while deci-ampere balance A is still in absolute agreement with the centi-ampere balance used to determine its constant. As regards the larger instruments, the results were equally satisfactory. Taking in the whole set of the seven standard instruments, the largest variation of constant for one instrument, when compared with the one next above it, was observed between the ampere and deca-ampere balances, and was then only $\frac{1}{60}$ per cent. Thus, at the time of writing, there was in the Physical Laboratory of Glasgow University, a series of standard instruments capable of measuring from half of a centi-ampere to 500 amperes, all of which were practically speaking in perfect agreement.

REVIEWS.

Practical Physics for Schools. Vol. I., Electricity and Magnetism. By Prof. BALFOUR STEWART, F.R.S., and Mr. W. W. HALDANE GEE. (London: Macmillan and Co., 1888.)

Shortly after the issue of the first volume of the "Elementary Lessons in Practical Physics," dealing with "electricity and magnetism," it was represented to the authors that that work might be made the basis of a class-book adapted for the use of schools. To this suggestion we are indebted for the very admirable little book now before us. The success of the earlier and larger volume has been so marked that no words of ours are necessary to commend the present version to the attention of every teacher of physical science. The value of these class-books, in the excellence of their illustrations and in the lucid exposition both of principles and of phenomena, is apparent, and still more, perhaps, in their insistence on the absolute necessity for the appreciation by the student at every stage of his progress of the quantitative relations involved in the experiments which he is called upon to perform. This feature, which is happily characteristic of the modern school of technical instruction, is in marked contrast with the style of most of the text-books of science of a few years since. "I should be glad," said the late Prof. Fleeming Jenkin in 1884, "if it were generally proclaimed that the elementary training in all our science laboratories should be training in the art of measurement. . . . . You may define the absolute unit of electrical resistance as accurately as you will, and your definition shall affect the average brain to no perceptible extent; but a young man of very ordinary education and intelligence can learn to measure resistances in ohms, and, having learnt this, an ohm becomes a reality to him; . . . [and] having acquired a working faith in the existence of ohms, he is prepared to take some trouble to understand the scientific definition." These wise words of Jenkin might have been placed as a motto upon the title page of these "Lessons;" indeed, so fully do the authors share in this spirit that the "school" version contains a good deal of additional matter, which is concerned almost entirely with the art of measurement. A new chapter has, for instance, been prefixed, under the title of "Introductory Measurements," and containing the following sections:—Units of Length, Area, and Volume; Use of Scales; the Vernier; Use of Callipers; the Micrometer Wire Gauge; the Standard Wire Gauge; the Balance; Method of Using the Balance; Estimation of Density and Time; Unity of Angular Measurement, &c.

The main body of the work is, as we have already intimated, an abstract of the earlier and well-known volume which was issued by the authors under a similar title twelve months ago, and we need therefore say little more about it, though it may perhaps be as well to add that there is nothing in the text to suggest the idea of an "abstract" in the sense of incompleteness. The experiments are described with the same careful elaboration as in the earlier work, and the excisions have chiefly taken place in the purely mathematical sections. A valuable appendix has been added, "On the Requirements of a Physical Laboratory." The equipment of three "model" laboratories is described, with ground plans of their fittings.

With regard to the arrangement of the book we might offer one word of criticism. The authors adhere to the well-established custom of commencing with static electricity, and devote a considerable space to this portion of the subject. We have recently given reasons for a view which we are inclined to hold somewhat strongly—*i.e.*, that static electricity should come last in order, and that the permanent magnet should itself be approached through the electro-magnet. We will only remark here that this is the order in which—as it appears to us—the pupil is least likely to have anything to unlearn as he advances, and in which the lessons may be taken in the most consecutive order.

It is impossible to lay aside this book without feeling an intensified regret that Professor Balfour Stewart passed away from us even before it had been issued from the press. It is to be hoped that his *collaborateur*, Mr. Haldane Gee, will yet carry on and complete the series.

On Difference of Current-Phase, Retardation by Induction and Dissipation of Energy in Transformers. By Prof. GALILEO FERRARIS. (Memorie della Reale Accademia delle Scienze di Torino. Ser. 2. Vol. XXXVIII.)

This is a reprint from the *Proceedings* of the Turin Academy, and contains an account of a theoretical and experimental investigation by Prof. Galileo Ferraris on some points connected with alternating currents. The practical value of the paper is largely discounted by the fact that the observations were confined to open-circuit transformers of the original Gaulard-Gibbs type—a type which it need hardly be said is now entirely obsolete. However, a brief account of the contents of the paper will probably be of interest to many of our readers.

Prof. Ferraris announces by a consideration of the method of determining the difference in phase between any two alternating currents, of the same period, by the use of the two coil dynamometer. This method is really due to Mr. T. H. Blakesley, and was first announced in the columns of this journal in 1885.* As, however, Prof. Ferraris makes no reference to Mr. Blakesley's work, we must presume that he has re-invented the method.

In Mr. Blakesley's memoir it is shown that if a be the ordinary dynamometer reading of the primary current, b the reading for the secondary current, and c the reading when one

* *Electrician*, 2nd October, 1885, p. 390.

Digitized by Google

current passes through the fixed coil alone, and the other at the same time through the movable coil alone, then, if ϕ be the angle of lag,

$$\cos\phi = \frac{c}{\sqrt{a\,b}}.$$

Professor Ferraris prefers to use three independent dynamometers, so as to take all the readings simultaneously.

The transformer used for the experiments was of the original open magnetic circuit Gaulard-Gibbs type, constructed for two horse-power, and had a movable core. The current was obtained from a Siemens alternating dynamo, and the electrodynamometers were of the form made by Siemens and Halske for use with strong currents. The table below, in which n is the number of revolutions of the dynamo, and r is the total resistance of the secondary circuit of the transformer, gives the results obtained in the first series of experiments :—

N	r	a/b	c/b	ϕ
603	0·409	1·026	1·010	175° 30′
605	3 224	1·215	1·054	162° 59′
601	5·713	1·561	1·082	150° 0′
609	8·542	2·152	1·109	139° 7′
610	11·000	2·923	1·142	131° 55′
6(2	14 790	4·969	1·203	122° 40′

Now, according to the elementary theory of the transformer (*see* Mascar et Joubert, "Leçons sur l'Electricité et le Magnétisme," Vol. I. p. 593 *et seq.*), based on the assumption that there is no retardation in the magnetisation and demagnetisation of the iron ; that there are no Foucault currents ; that the coefficients of induction are constant, and that both the primary and secondary currents are sinusoidal, a/b, c/b and ϕ should be constant, whereas the table shows that they are functions of r. The discrepancy cannot be due to variation in the coefficients of induction as the saturation of the iron diminishes, for in that case their ratio would be constant, which would make these three columns constant. The author therefore considers the theory of the transformer when magnetic retardation is taken into account, and finds that the experimental results then show a very close agreement with his theory. He points out that one cause of the retardation is hysteresis in the iron, and he then proceeds to investigate the effect of the Foucault currents. These in their generality cannot be submitted to analysis, but he obtains a first approximation to their action by considering the action of a single alternating current through the core and other metallic portions of the transformer, and he shows that its result would be to cause an additional retardation, and he finds by experimenting with different cores that the retardation from this cause is diminished by increasing the internal resistance of the core, which is not perhaps a very novel conclusion.

The author shows that a very simple relation exists between the dissipation of energy and the retardation of the secondary current, namely, if we write $\frac{\mu T}{2\pi}$ and $\frac{\lambda T}{2\pi}$ for the coefficient of mutual induction of the two coils, and the coefficient of self-induction of the secondary coil respectively, the values being those obtained experimentally with alternating currents, and if P be the amount of energy dissipated, and Q the amount developed in the secondary circuit in the same time, r the resistance of the secondary circuit, and if τ be the retardation, then approximately

$$\frac{P}{Q} = \frac{r}{\lambda}\sin\frac{2\pi}{T}\tau = \frac{\mu}{\lambda}\left(\frac{c}{b} - \frac{\lambda}{\mu}\right)$$

So that within the limits between which $\frac{1}{\lambda}\cdot\sin\frac{2\pi}{T}\tau$ is practically constant, the ratio P/Q is simply proportional to r; but the former quantity increases as r increases, so that as r increases the ratio P/Q increases more rapidly. The expression for P/Q shows that for a given value of r and a given transformer the loss of energy is diminished by increasing the speed of alternation, and also by increasing the self-induction of the secondary coil. It also follows that the efficiency determined for a given speed of alternation will not give the value for another speed of alternation, which is, however, obvious from quite elementary considerations.

The author determines the ratio P/Q for a value of $r = 6$ ohms, and with the same speed of alternation with five different cores, and found results of the kind which might readily have been predicted. With a well laminated core the ratio $\frac{P}{Q}$, or $\frac{\text{waste}}{\text{work}} = 0{\cdot}07$, and with a solid bar of iron it rose to 0·9.

INSTITUTION OF MECHANICAL ENGINEERS.

THE POSITION AND PROSPECTS OF ELECTRICITY AS APPLIED TO ENGINEERING.

BY MR. W. GEIPEL.

At the forty-first annual general meeting of the Institution of Mechanical Engineers, held at the Institution of Civil Engineers, Mr. WILLIAM GEIPEL, of Edinburgh, read a paper, of which the following is an abstract :—

In the present paper the author purposes confining his remarks to those branches of electric engineering which involve the employment of considerable power and are in some way connected with the use of dynamo machines. The principal of these may be treated under the four following heads :—

I. Electric Transmission and Distribution of Power.
II. Electric Locomotion.
III. Electric Lighting.
IV. Electric Metallurgy.

I.—ELECTRIC TRANSMISSION AND DISTRIBUTION OF POWER.

In the near future this branch of electric engineering will probably occupy more attention and call forth more outlay of capital than either of the three others mentioned above ; already, indeed, it is commanding a great deal of attention. Owing to its simplicity, the ease with which an electric motor can be applied to any purpose requiring power and its high efficiency, is certainly an approach to an ideally perfect system of transmission. No greater contrast can be imagined than the difference between the position of electricity in this country and in America. On the other side of the Atlantic, although the science of electricity is much behind, the practice is far ahead of our own. European science has supplied an agent, the value of which has been recognised by American engineers ; and now in the United States the applications of electric motors are already rivalling and will soon excel in importance the application of electricity for lighting purposes. It is to be remembered, however, that there, owing to the high price of coal, the use of steam-power is a more serious consideration than here ; they have also in many places abundance of water-power which can be utilised by electric transmission. Notwithstanding these differences, there is in our own country an almost unlimited field for the employment of this mode of transmitting power cheaply to a distance, and of distributing power generated at a central station to a number of users in the neighbourhood.

Were it not for the cost of the dynamos and motors, electricity would supersede to a great extent the use of belts and shafting. In large works, where high speeds are required and the demand for power is variable, the efficiency of belts and shafting is very low indeed. As much as 25 per cent. of the power may be absorbed by the shafting when the full number of machines are in use ; and in such a case with half the machines in use the loss of power rises to nearly 50 per cent., while in the extreme of driving only a single machine even 99 per cent. may be lost. With electricity, on the other hand, no power is being used in keeping the transmitting medium in motion, the conductor being stationary ; the loss takes place only whilst power is actually being used by the motors, each of which drives its own machine. In fact, the percentage of power lost in the transmitting medium becomes smaller as the amount of power transmitted is reduced, which is exactly the converse of what happens with belting and shafting. For the sake of illustration and comparison, let it be assumed that a loss of 25 per cent. of power would take place in the electric conductor when the full load is on ; although in reality the loss would never be above 10 per cent., and need not be more than 5 per cent. Then with half load the loss would be 12½ per cent., and so on ; and with one machine possibly one-tenth of 1 per cent. might represent the loss in the conductor. When it is remembered in how many cases the average load in a factory is less than half the maximum, it is evident that this point is one demanding the greatest consideration. In New York, where a large number of motors are supplied with current from the electric light mains, it has been found by experience that on an average less than one-third of the whole number of motors are in use at any one time.

Digitized by Google

The depreciation of the electric conductors is comparatively small; but whether the saving of renewing belts and of lubricating shafting would not be counterbalanced by the wear and tear of motors is a question to be settled by individual experience. The advantage, however, of getting rid of shafting, thereby obviating the necessity for additional stability in the building and doing away with constant lubrication, and the further advantages of saving the space and light absorbed by belts, and of the ease with which the conductor can be shifted to suit any desired alterations in position of machines, are also very important matters.

The distribution of power by electricity from a central station to small users will, in the author's opinion, form in many towns a larger business than the lighting. Both can be done from the same mains and generators, just as is the case with gas; it is merely a question of economy and convenience as to whether gas or electricity should be used. The encouragement of small industries has long demanded some cheap means of obtaining power in small quantities, say from ½ to 25 horse-power. The gas engine has not altogether met the requirements of small establishments, although needing but little attendance; for the first cost of even a small engine is high, and the amount of gas consumed is large. Moreover, the speed is generally irregular, owing to the intermittent impulse, which is more especially noticeable with light loads; and a considerable amount of wear and tear takes place in the valves and working parts.

An electric motor can be started and stopped at will with the greatest ease; it requires the smallest amount of attention, occupies the minimum of space, and can be placed in almost any position. An ordinary shunt-wound motor will run at an almost constant speed, with a maximum variation of only 5 per cent. from running light to fully loaded; this fact was first pointed out in an interesting paper in the *Philosophical Magazine* for January, 1886, by Mr. Mordey, who has done much valuable work in the perfecting of the modern dynamo machine; he has kindly sent me a diagram, showing the result of some tests of a Victoria motor for change of speed under variable load, which illustrates the remarkable constancy of speed attained. This exceedingly close regulation was obtained by using a simple shunt motor of suitable construction, and without any accessories such as the many forms of governing devices to which so much attention had previously been devoted. The result shows that such a motor possesses a practically perfect power of self control, not only over its rate of speed with varying load, but, what is of equal importance, over the energy absorbed by it; for it helps itself, as it were, to only such an amount of energy as will enable it to deal with the work imposed on it. A 1 horse-power motor will cost £20 against £100 for a gas engine. The cost of running a gas engine is about one penny per horse-power per hour for gas alone; the same power generated by a dynamo driven by an efficient steam engine costs only about one farthing, current being supplied from street mains just as gas is.

As small steam engines are being superseded by gas engines wherever the outlay for the latter can be afforded, the competition in regard to small powers lies between gas and electricity, and steam may be left out of the question. There is, of course, a limit above which steam becomes the cheapest; and probably 10 horse-power may be taken as about that limit in this country. In Boston, in the United States, where some hundreds of motors are supplied with electricity from central stations, they range from half to 15 horse-power, and are working lifts, printing establishments, small machine shops, and watch-making, tailoring, boot-making, and similar industries. Their working seems to be highly appreciated; and the author understands the users would be willing to pay even 25 per cent. more for them in consequence of their convenience and regularity in working. In Geneva,* within a radius of a mile and a quarter there are no fewer than 175 motors at work, varying from ½ to 70 horse-power, supplying power to small workshops, and for other purposes, the electric power being obtained from dynamos and turbines, which are driven by water power derived from the Rhone. The installation is paying its way, and is about to be largely increased. At the Falls of Niagara plant is being put down to distribute power obtained from the Falls to neighbouring towns, including Buffalo, which is twenty miles distant; the amount of power is stated at 15,000 horse-power, of which 10,000 horse-power is contracted for at £3 per horse-power per annum for power and lighting purposes in Buffalo.

As an interesting example may be mentioned a 6 horse-power motor recently erected by the Brush Company of Cleveland, Ohio, in a printing establishment, where it was connected with the regular arc-light circuit. It takes the place of a 10 horse-power steam engine, which had sometimes come to a standstill under its load. It drives about 70 to 80ft. of shafting, three cylinder presses, four platen presses, one large paper-cutter, and one very heavy lift; and by a 4in. belt carried up through three floors it also drives three ruling machines and four paper cutters. It does its work splendidly, and its motion is steady and regular. It has proved to the proprietor's satisfaction that printing offices could well afford to employ electricity instead of steam, even in cases where the first cost might be more. In many other towns in America, where the electric-light mains are within reach, the number of motors already in use is very great; within two years 5,000 motors have been supplied by one firm alone, and the author understands that the Brush Company are turning out as many motors as dynamos.

In some places in this country, and more especially in Lancashire, it is customary for power to be supplied from a large steam engine to neighbouring buildings, which are let out as separate workshops. In such instances, however, the power supplied is more frequently above than below 10 horse-power, and probably it would not pay to introduce an electric motor. Still, it should not be forgotten that in renting these workshops considerable inconvenience may be incurred as regards the locality of the premises for the manufacture; moreover, the rent is often disproportionately high.

Many schemes have been propounded for distributing power in manufacturing districts by means of steam, compressed air, and water pressure, each of which is in use to a somewhat limited extent; and as all of them have been known long enough, it may seemingly be inferred from their limited employment that there is not much to recommend their extended use commercially. With steam, the condensation in the pipes causes loss of pressure, and results in wet steam being supplied to the engines. Compressed air cannot efficiently be worked expansively, and is attended with loss of heat in the compressor. Water pressure commonly involves using the maximum power, whatever the work required. Besides these prominent faults of the three several methods, what is of the greatest importance and common to all three is that the generating plant has to be used almost exclusively for supplying the power, and cannot be utilised for other purposes in addition; whereas with a central electric station the engines and dynamos serve to generate current for lighting purposes also at night.

Collieries.—In collieries electricity will be largely adopted in the near future. For underground hauling, pumping, ventilating, and drilling, it can readily be applied with an efficiency double that of compressed air. With a well-arranged installation 75 per cent. of the brake power of the engine will be utilised on the shaft of the motor.

For hauling and pumping, wire ropes or rods are the greatest competitors of electricity, which obviates the following disadvantages in connection with them: chance of breakdown through strain; wear and tear; mishap to guides through falls of roof or dirt; trouble and expense of oiling the guides; and room required at pit mouth or at bottom for engine, pulleys or levers, or other gear. As the tendency in mines in this country is towards a reduction of working hours, the question of mechanical haulage becomes most important, because horses must be fed whether at work or idle, and the cost of haulage by horses therefore increases as the working hours become reduced.

For ventilating and drilling, compressed air is perhaps most largely used; and one of the great points in its favour is that the exhaust is available for supplying fresh air to the miners, and for driving out the foul gas after the firing of shots. But the cost of the compressed air machinery is heavy, as is also that of the pipes for conducting the compressed air from the compressor to the place where it is used. The cost of electric plant is somewhat less, and the efficiency is very much greater; while by using old haulage ropes as conductors the cost of this item is rendered very small.

At Trafalgar Collieries, in the Forest of Dean, there is an interesting instance of pumping on a small scale.*

Another interesting example of pumping is afforded by the recent introduction of electricity for this purpose into St. John's Colliery, Normanton.†

At Thallern Colliery,‡ on the Danube, where electricity has replaced steam for pumping, it has been found after several months' work that a considerable saving in coal is effected; also that the temperature of the pit is reduced some 14deg. F., steam having previously rendered the atmosphere of the mine unbearable.

In the mines of Blanzy,§ in France, a ventilating fan is driven from a generator at bank. The fan is 150 yards in, 2½ft. diameter, by 11¾in. broad, and runs at 730 revolutions per minute. The temperature at the face has been reduced 15deg., from 95deg. to 80 deg. F., since its introduction.

Shipyards.—In shipyards and similar works electricity has already proved itself a suitable and economical means of transmitting power for riveting, drilling, &c. The electro-magnetic tools described in Mr. Rowan's paper at last year's summer meeting (*Proc.* of Mechanical Engineers, 1887, page 323)‖ are being successfully employed in yards at Dumbarton. This system possesses the

Digitized by Google

additional advantage that the tool can be firmly held to its work by magnetic attraction alone, without the use of bolts, so that no holes need be left for hand riveting as is required with other machine riveters.

Transmission to Great Distances.—The transmission of power to great distances is not of such vast importance here as in the colonies, although even in the small sluggish rivers of this country there are large amounts of power running to waste. In many places where works have been erected for utilising water-power, it has been at the sacrifice of convenience of situation, or of a ready and cheap means of receiving and despatching goods; whereas by means of electricity the same water-power might have been transmitted to a locality more suitable for the works. For short distances it does not pay to transmit water-power by electricity, owing, as previously mentioned, to the cost of dynamos; in such cases transmission by shafting or wire ropes is cheaper. But for long distances shafting is out of the question, wire ropes become more expensive, and electricity is cheapest.

As an interesting instance of the transmission of power by electricity over long distances, that at the Phœnix Gold Mines* in New Zealand may be referred to. The current is generated by two No. 8 Brush machines, each capable of giving 20,000 watts or 26 horse-power; they are driven by Pelton water wheels, with a head of 180ft. The current is conveyed to the motor about three miles distant, and back again, by a No. 8 B.W.G. copper wire (0·165in. thick) nearly six miles long, supported on telegraph poles. The power lost in the line is only 3 horse-power. A Victoria motor is used, running at about 350 revolutions per minute; and the power is transmitted to the machinery by a belt.

Mr. C. E. H. Brown, of Oerlikon, has succeeded in transmitting by electricity 50 horse-power from water at Kriegstetten over a distance of five miles to Solothurn in Switzerland, with a commercial return of over 70 per cent. Two series-dynamos and two series-motors are arranged on the three-wire system. Each of the three wires is ¼in. diameter, consisting of bare copper suspended on poles about 40 yards apart, with fluid insulators for ensuring good insulation. For a span of 130 yards across the River Aare, silicium-bronze wire is used, which has the same conductivity as copper and a tensile strength of 30 tons per square inch. The current used is 15 amperes, and the potential difference at the terminals of each dynamo is 1,250 volts. The resistance of the line is 10 ohms, and the loss in it is a little over 3 horse-power, or 6 per cent. of the total power. The loss in dynamos and motors is 24 per cent., being much less than in Deprez's machines, where it was 44 per cent.

At Hatfield, on the Marquis of Salisbury's estate,† the River Lea is utilised to generate electricity, which is transmitted to the house and over the estate for a variety of purposes. Two turbines are used—one to drive a 40 horse-power Siemens alternating-current dynamo, for lighting the house; and the other to drive a 16 porse-power Brush machine, for arc-lighting at night, and in the day for working the motors at the house and on the farm. Those at the house drive pumping and ice-making machinery, and a 24in. Blackman air-propeller fixed in the roof for ventilating; on the farm the motors are used for elevating hay and corn sheaves to the tops of the stacks, for thrashing, for cutting rough grass with a chaff-cutting machine for ensilage, in fields extending to a distance of two miles, for grinding corn, &c., to make fodder, and for other purposes. The motors have also been used for pile driving, for making cofferdams where necessary in the river; and also for dredging the river and clearing it of weeds. A Gramme motor, capable of raising 2,500 to 3,000 gallons per hour, pumps the town sewage into a tank at a height of 30ft. for irrigation. The conductors are carried overhead on poles about the farm, and underground in wooden troughs to the house.

II.—Electric Locomotion.

The practical methods of accomplishing electric locomotion seem to the author to be the four following:—

Firstly, the use of a third insulated rail or conductor to convey the current from the generator to the motor carried on the locomotive, contact being made by a wheel or a sliding spring or brush; while the two ordinary rails serve as a return circuit, the current being conducted from the motor to the rails through the frame, axle, and wheels of the locomotive.

Secondly, the employment of an overhead conductor supported on poles or from the roof of an arch or tunnel, contact being made either by a carrier on wheels running along the conductor, or by rubbing. The return circuit may be either through a second overhead conductor or through the ordinary rails, as in the third-rail plan.

Thirdly, the use of an underground insulated conductor, placed in a conduit between the rails, and conducting the current from the generator through a contact carriage to the motor, whence it is conveyed back through the frame, axle, wheels, and rails.

Fourthly, the employment of storage batteries, placed preferably under the seats of the car with the motor and gear underneath, or the whole placed on a separate locomotive.

The plan of using the ordinary rails as positive and negative conductors, and insulating the wheels or axles of the car, is attended with the objection that, owing to the rail supports having to carry heavy loads, there is difficulty in insulating the rails sufficiently to prevent excessive leakage to earth.

Of these four methods the first two are the cheapest and most efficient, but are applicable only to railroads; while the two other plans, of an underground insulated conductor and of storage cells on the car, are both applicable to street tramways.

Gearing.—Owing to the high speed at which electric motors require to run, and the limited space available for them to occupy, the mode of gearing the motor to the axle of the locomotive or car forms an important consideration, more especially in places where the motor is placed upon the car which carries passengers, when noise and vibration would be most objectionable. The following five methods of gearing are those more generally employed:—(1) worm-wheel gearing; (2) pitch-chain gearing; (3) leather belting; (4) rope, either endless or not; (5) toothed wheels.

Worm gearing appears from Mr. Holroyd Smith's experience at Blackpool,* where his electric tramway is worked with an underground conductor, to be the best for tramcars. Although as a rule it is not efficient, yet if well designed and properly lubricated it can be rendered more efficient, and probably is fairly suitable for this purpose. Some tests made by Mr. Reckenzaun show a maximum efficiency of 87 per cent. The author thinks that a combination of toothed wheels and friction gear, such as has been introduced by Mr. Raworth for driving dynamos in electric lighting with excellent results where space is a desideratum, would make a silent working and durable form of gear; the friction gear would serve to reduce the speed from the motor to a countershaft; and from the latter the driving wheels of the car would be driven by toothed wheels. The form of gear employed of course depends greatly upon the nature of the traffic and of the rolling stock.

Third Insulated Rail.—As an example of an electric railway with a third insulated rail, that at Portrush, Ireland,† is probably the most interesting, as being one of the first started in the world and also the longest; its total length is six miles. Power is generated by two 50 horse-power turbines, driving a dynamo which is capable of generating 100 amperes at 250 volts; the current is transmitted from the River Rush through a distance of 1,600 yards to the railway, the resistance of the line being 1·9 ohm. Pitch-chain gearing is used, and gives satisfaction. The working expenses amount to less than threepence per car mile.

Another instance, also in Ireland,‡ is the Bessbrook and Newry tramway, which is three miles long and 3ft. gauge, and is actuated by water-power. The accompanying photographs showing the arrangement of the cars have been kindly lent by Dr. Edward Hopkinson, to whose designs the railway was constructed. A turbine which develops 62 horse-power drives two Edison-Hopkinson dynamos, each capable of giving out 25 horse-power at 250 volts. The third rail is of channel-section steel, supported in wooden blocks which apparently act admirably as insulators, the leakage being only ½ ampere per mile, or 0·3 horse-power in all. A train consists generally of one passenger car constructed to carry thirty-eight persons, and three goods waggons, each carrying 2 tons freight. The maximum speed that can be attained is 15 miles per hour. Here also chain gearing is employed. The cost per train-mile is 3·3d. during the busy months, and 4·2d. in slack months; these figures, however, do not include anything for depreciation on the cost of construction of the railway, which was £2,500, nor for general supervision.

Overhead Conductors.—The electric railway at Moedling, near Vienna, is a good example of the employment of overhead conductors. The number of passengers carried during the year 1886 was 342,257, according to Mr. Reckenzaun, and the average cost 3·42 pence per car-mile; the coal consumption per car-mile was 13·4lbs. of very inferior brown coal. The current is generated by six Siemens dynamos, driven by three portable engines of 12 nominal horse-power each; the use of these engines may account for the somewhat high consumption of coal. The overhead conductors, which are carried on posts 18ft. high and 90ft. apart, consist of slotted tubes in lengths of 15ft. each, soldered together; a contact carriage slides within the tube, which is 1in. diameter inside. Spur gearing is used, but apparently is not satisfactory; the objections to it are the rapid wearing out of the high-speed pinions, the great weight of the gear, and the noise and vibration caused.

Digitized by Google

The Frankfort Offenbach* electric railway, which was opened for traffic on 10th April, 1884, is similar to that at Moedling, the current being brought to the moving cars by means of slotted iron-tube conductors carried overhead. The length of the line is about 4½ miles; the gauge is 1 metre (3ft. 3⅜in.). The sharpest curve has a radius of 98½ft.; the steepest incline is 1 in 30, and only 18 per cent. of the line is level. The average speed of the cars is 7½ miles per hour. Two cars coupled together start from each end of the line every twenty minutes. Each car has seats for eighteen passengers and standing room for twelve more, the gross weight being four tons. The motor is placed under the floor of the car, and the connection to the wheels is made by toothed gearing. The generating station is at Ober-rad, about the middle of the line, and contains one twin engine of 240 indicated horse-power, and one spare engine of 80 to 100 indicated horse-power; in regular work one cylinder only of the twin engines is used, giving off 120 indicated horse-power. The current is generated by three Siemens dynamos, called 300-light; a fourth similar dynamo is in reserve. The working electromotive force is 350 volts. The current generated by the three dynamos is sufficient to keep eight cars running simultaneously.

This plan has been most largely adopted in America, where there are probably not far short of one hundred electric railways at work and projected. It has certainly the recommendation of cheapness, for a higher voltage is permissible, and consequently a smaller conductor with less loss of power than in the case of the third rail; this is more especially important for long lines. As an instance of what is being done, a railway of eleven miles length is now in course of construction at Richmond, and forty cars are building to be worked upon it on the overhead system. Another instance is the railway at Scranton, Pennsylvania, which has been in successful operation about a year. It is 4½ miles long, five cars carrying motors from 15 to 20 horse-power are in use, and four cars with 25 horse-power motors are being constructed, each of which will be able to draw two others; the cars carry seventy-five passengers each. The current is generated by two 100 horse-power dynamos, driven by two 180 horse-power engines, one set being spare; the potential adopted is 600 volts. The overhead conductors are of copper $\frac{5}{16}$in. diameter; the supporting poles are 100ft. apart, about 20ft. high, and about 6in. diameter at the thick end; the return circuit is through the ordinary rails. The plant is also used for lighting the town. The potential generally employed in America for the longer lines is from 500 to 600 volts; the latter is probably the limit to which it is safe to work. With this potential two ⅜in. copper conductors would serve to work twenty-five cars in parallel, the current per car averaging about 10 amperes. With a voltage as high as this the leakage on the third-rail system would be excessive.

Underground Conductor.—Perhaps the most important example of this plan is Mr. Holroyd Smith's electric tramway at Blackpool,† which has been in successful operation for some two years. The underground conduit is somewhat similar to that of a cable tramway such as is working at the present time in Edinburgh and on Highgate-hill, London; but instead of the carrier being used to grip a running cable, it is made to rub along a stationary conductor. The cost of working is stated to be less than fourpence per car-mile; during one week in the season of 1886 there were 44,306 passengers carried at a cost of £45 for wages and fuel, which is less than one farthing per passenger.

Where an underground conductor is employed, the advantages of having no slit communicating with the surface of the street are so obvious that an ingenious plan has been proposed by Mr. Frank Wynne for placing the conductor in a hermetically sealed conduit under the line.‡ A small carrier, which acts as a contact-maker between the conductors and short sections of rails laid in the road, travels along the conduit, being actuated by a tiny electrometer and by part of the same current which works the tramcar above it. An absolute synchronism between the tramcar and the carrier is obtained by a simple device. The short sections of rails are in circuit only whilst the car is over them.

A plan has been proposed by Messrs. Ayrton and Perry§ for making contact between the underground conductor and the section of rail underneath the car by means of the weight of the car, which actuates an arrangement of levers that make the contact so long as the car is on that section. A plan has also been proposed by them for employing the attraction of a magnet fixed on the car, and keepers fixed in boxes underneath the street. The contacts on the keepers are permanently connected with the underground conductor, and when lifted by the attraction of the magnet on the car they make connection with a section of rail, putting the motor in circuit.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

STUDENTS' MEETINGS.

At a meeting of students on January 19th, F. H. Webb, Esq., presiding, the report of the committee was read and adopted, also the following gentlemen were elected to form a Students' Committee for 1888:—

Mr. C. G. Lamb, B.Sc., Mr. R. W. Paul,
Mr. Chas. Priest, Mr. E. G. Tidd,
Mr. J. N. Cooper, Mr. A. G. Sanders.
Mr. J. Rance, jun., Hon. Sec.

Mr. J. N. Cooper then read a short note upon "An Error Due to Refraction in Mirror Galvanometers." A short discussion followed, in which Messrs. Paul, Smith, and Lamb took part.

February 2nd.—Prof. J. A. Fleming, D.Sc., in the chair. Mr. C. G. Lamb, B.Sc., opened a discussion upon the recent papers on voltmeters. Messrs. Gimingham, Smith, Bate, Paul, Dykes, Cooper, and Dr. Fleming discussed the subject, and after Mr. Lamb's reply the meeting was terminated by thanking Dr. Fleming for presiding.

The council of the society has resolved that students tranferred to the class of associates shall be permitted to attend students' meetings for one year after the date of such transfer.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *Jan. 28th*, 1888.

Dr. Norvin Green, president of the Western Union Company, who has just appeared before the Post Office Committee of the United States Senate, expresses his belief that we shall have no Government telegraphs in this country at present. Although considerable agitation on the subject is going on, he believes that the actual sentiment in favour of the scheme is really not so great as it once was. In the course of his evidence he pointed out that the average cost of a message to the public had fallen from $1.05 in 1867 to 30½c. in 1887, and he volunteered the information that rates are to be reduced again this year. He also believed that the deficit of such a Government system as has been suggested would be from $5,000,000 to $10,000,000 annually. He asserted that under a Government system no compensation was made to aggrieved parties for "bulls" and blunders in their messages, whereas the Western Union Company paid out from $100,000 to $200,000 a year under this head of expenditure. He characterised Governmental telegraph service as being generally poor and inefficient, and he held that if the Western Union Company be a monopoly—which he denied—its control of vast capital and plant had enabled it to do work that was without parallel anywhere. He mentioned also the interesting fact that no fewer than 3,000 people directly, and 20,000 indirectly, are interested in the stock of the Western Union Company. Dr. Green was followed by Mr. Gardiner G. Hubbard (the father-in-law of Prof. Bell), a gentleman greatly interested in the subject of postal telegraphs. It might be supposed that Mr. Hubbard's pecuniary interest in the telephone would give him some opinion of this subject, but whatever the reason of his advocacy there can be no doubt that Mr. Hubbard is very much in favour of Government control of the telegraphs. His idea is that the Post Office department should receive telegrams, just as it does letters, that it should further make a contract with competent parties to transmit the telegrams, and that the Government should then deliver the telegrams, the post office in country towns being also, as in England, the telegraph office. All telegrams are to be prepaid on this system by Government stamps. He advanced various arguments, more or less familiar, in favour of this plan, and made the statement that while it was true English operators were paid less than American, the American offset this by sending 2,500 words to the Englishman's 800. What have your readers to say about that?

Digitized by Google

Speaking of the juxtaposition of these two gentlemen in Washington, reminds me that wild rumours have been afloat during the past week as to an approaching rupture between the American Bell Telephone Company and the Western Union Company, the ground of trouble or warfare being the continued extension of the long-distance telephone lines. One of the reports in circulation went so far as to allege that the Western Union Company intended to take up the McDonough telephone and use it as a weapon against the Bell Company. It will be remembered that the Western Union Company is not a stranger to the telephone business, but had at the time it made its compact with the Bell Company a large number of exchanges in operation. It is generally understood that the McDonough telephone stock is held largely by Mr. E. S. Stokes, who is now at the head of the Postal Telegraph Company, which has some kind of working arrangement as to rates with the Western Union Company. I need hardly say that all these rumours have been very positively contradicted; but there are a good many people who believe them on the ground that where there is smoke there is fire. There seems to be no question as to the preference given to the telephone over the telegraph for private lines, and the long-distance company in New York has now a large number of such lines in operation.

I made note some little time ago of the onslaught of the newspapers in Chicago upon the local telephone company. The scene now shifts to St. Louis, where a movement has been begun to cut the rates in two. A petition, signed by a large number of the leading firms, has been addressed to the municipal authorities, asking that a Bill or ordinance be passed fixing the rate at $50 a year instead of $100. It is not known how far this agitation is likely to be successful. It is safe to say that the local telephone company will resist it. The Law switch-board system is in use in St. Louis, and from personal observation I can say that the service is excellent. Mr. Durant, the manager, is an enthusiast about his work, and spares no pains to treat his *employés* well, or to please the public. Ever since the destruction of his central office by fire in 1885 he has been hard at work increasing the efficiency of his system, and it seems a little hard that just as he has succeeded he should be met with this attempt at a reduction of rates. The exchange has, I believe, about 2,000 subscribers, and its list of the daily work of the exchange averages 15,500 connections, bringing 31,000 stations into use. Mr. Durant is quite statistically inclined, and has recently constructed a chart showing the fluctuations in five-minute periods of 10 hours' traffic from a group of 89 subscribers. The average number of the connections as the result of the experiment was—per minute, 1·94; per five minutes, 9·72; per hour, 116·7.

A large number of motors are now being installed in this city, and the prospects are that the demand will increase very rapidly. In one case, where an isolated Edison plant is to be put into some large car stables, Sprague motors are to be used for running the elevators, cutting the hay, and driving various machinery in the blacksmithy and the forge shop. In this way the plant will do double service, and a little bit later we may expect to see it charging batteries to drive storage cars on the road. Another case of novel work is that mentioned in the motor catalogue recently published by the Brush Electric Company. A Brush motor drives the dough mixers in a large bakery, taking its current from the street circuits, and the parties who use the motor are very well satisfied with the results obtained. A suggestion is now being made that the fire departments, instead of using steam engines, should resort to electric motors for attaching the pumping apparatus, and it is not at all unlikely that something of the kind will be tried; in fact, a departure in this line has already been made by the Sprague Company, which is building a stationary electric motor fire outfit for the palace of the Mikado of Japan. The growing importance of electrical enterprises is now recognised by the public and by legislators, and the latest sign of this appreciation is found in a Bill introduced into the New York Legislature which proposes to place all the telephone, telegraph, electric light, and other companies under the care of a commission, which is to consist of eight members to be nominated by the governor and confirmed by the Senate. This Bill was before the Legislature last year, but is revived this, and, it is said, with more prospect of success. In Massachusetts the electric light companies are placed under the supervision of the gas commissioners, who have made their report this week, to the effect that in that one little State there are no fewer than fifty-six companies now engaged in supplying electric lights.

Now that we have our subways we are beginning to experience some of the troubles and drawbacks that attach to them. Last week a bad accident occurred in one of them on Sixth Avenue uptown, where two men, working in a manhole, became suffocated by the illuminating gas that had leaked in, one of the men being dead when taken from the hole. So great is the accumulation of gas that when working in these manholes it is necessary to fan it out; but on this occasion, the weather being extremely cold, the precaution was neglected. It has begun to be feared that New York will have the experience that other cities here have already enjoyed, of seeing its electrical subways damaged by frequent gas explosions, with serious results.

I do not know whether you in England attach much importance to methods of refining sugar by electricity, but here the project has been brought up again in tangible shape, and the Electric Sugar Refining Company is reported to be getting a factory ready in Brooklyn, where it will use the Friend electric process, whatever that may be. The capital stock of this company is £200,000, held, so the story goes, to some extent in Liverpool, by persons interested in the sugar industry. We are told that this remarkable system will knock beet sugar into a cocked hat, and that it will refine a ton of the worst raw sugar that the West Indies or Java can produce into perfectly hard white sugar. A ton of raw material can be thus converted in two hours at a cost of 80 cents a ton, and this company is reported to be getting ready to turn out 3,000 barrels of crystallised sugar a day. The project is viewed with a great deal of scepticism, but if sewage can be refined, why not sugar?

The cable steamer "Minia," which has been in dry dock so long here repairing after damage in the North Atlantic, has taken her departure for Halifax. It is understood that she will be actively engaged on important grappling work early in April. The visit of the steamer to New York has been quite a pleasant episode, and Captain Trott and his officers have left an extremely favourable impression behind them in electrical and other circles. Captain Trott's opinions on all subjects connected with navigation, as with cable laying, are of the utmost value; and I understand that while he was here he was consulted by some of the leading shipowners and their representatives as to the best course for steamers to take between England and America. Whatever advice he gave is sure to be followed. I understand that one very pleasant afternoon was spent by him at Mr. Edison's new laboratory, where he and the distinguished inventor exchanged their views on the subject of insulation for wires and cables. Captain Trott also, while here, paid considerable attention in leisure moments to the subject of electric traction, riding on the storage cars, and taking the opportunity to visit the Jamaica Long Island Electric Railway.

CORRESPONDENCE.

THE POST OFFICE AND THE TELEPHONE COMPANIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In course of your very interesting article last week on "The Postmaster-General and the Telephones" there has crept in one or two material inaccuracies, which I trust you will allow me to correct.

Speaking upon the question of whether there is or is not

Digitized by Google

"competition" between the Government Department and the private companies, you say :—

"As a matter of fact, there is no competition between the parties. . . . . On the part of the Post Office there is virtually no competition at all, and, except in one or two isolated places, the department has had no opportunity of showing the public what the telephone is capable of if taken in hand solely in the public interest and not as a commercial speculation.

"Obviously the State can never risk public money by competition, in the ordinary business sense of the term ; and in this particular case the Post Office was utterly disabled from doing so by the fact that it accepted a royalty on the business of all its possible competitors. To take the royalty and try to acquire the earnings would have been in the highest degree unfair, and the result has been that the companies have had a free hand, hampered only by the condition that, for depriving the Post Office of what the law had declared to be its legitimate business, a portion of their receipts should be handed over to the public revenue."

1. Now, there can be no doubt as to the existence of competition between the Government and the telephone companies. The Post Office competes keenly for private line business, and also competes in *trunk wire* business, as for instance between Manchester and Liverpool.

In their turn, the private companies—by means of their trunk wires—compete in a rapidly increasing degree with the Postal Telegraphs.

In my company's district alone more than 50 per cent. of our subscribers make regular use of the inter-town system of communication, and the average number of trunk wire messages reaches 3,000 per day, as against 25,000 purely local. When estimating the monetary value of these telephone messages, it would be far wide of the mark to consider them as just so many sixpenny telegrams lost.

The telephone message is not limited, like the telegram, to a dozen words for sixpence. Three minutes' conversation is allowed, which, practically, is equivalent to a long telegram with a prepaid reply.

2. The telephone companies have *not* got a "free hand." How can they have when, in addition to paying their Government rival a "bounty" of 10 per cent. upon gross "exchange" receipts, that rival is empowered to dictate what shall or shall not constitute legitimate telephone business ? To take only one instance, my company has for a very long time been desirous of adopting a message system, as existing in the United States, but the Postmaster-General steps in and, in his license, vetos our power to traffic in "written messages." So far is this prohibition carried, that the department complained strongly at the last General Election of our transmitting results of the poll from one town to another, although such results, once made public in any town, became common property.

There are several interesting points for discussion that occur to me in connection with this topic, but I fear I have already trespassed unduly on your space.—Yours, &c.,

KENNETH MACIVER, Sec. and Gen. Manager.

Lancashire and Cheshire Telephonic Exchange Company (Limited),

38, Faulkner-street, Manchester, Feb. 8th, 1888.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : I agree with your opinion expressed in your leading article, that it is somewhat rash to infer telephone companies' shares will gain by our Post Office acting on the line of policy indicated by the Postmaster-General's speech.

Suppose negotiations should be entered into for this purpose, the question will arise, What have the telephone companies to sell ?

Firstly. Two master patents, which will expire in two or three years.

Secondly. Telephone exchanges in all the principal towns, including plant lines, way-leaves, and probably goodwill of same ; also some long-distance trunk lines between towns.

Thirdly. Concessions given by the Postmaster-General which have to run for about thirty years ; but as the concessions are not exclusive, I take it their value, especially to him who has granted them, cannot be very great.

Fourthly. Commercial goodwill. The telephone companies have not fostered the establishment of a trade, either manufacturing or commercial, in the United Kingdom ; on the contrary, their policy has been decidly in the opposite direction. Such a goodwill, therefore, can hardly exist.

Fifthly. The chances of the Bell-Edison patents being renewed. Mr. Moseley tells us that the telephone companies indulge in some hope that their rights will be renewed. If they should apply for renewal, it is very certain that they will encounter determined resistance from the public, to whom they have shown few favours ; and from the electrical trade, whom they have treated in a spirit of unaccountable shortsightedness, which will be apparent to them whenever the time comes.

It appears to me, therefore, that the telephone companies have to offer nothing but patent rights for a very short period and the plant, &c., of their exchanges.

Now, the capital of all the companies (taken from a book edited by Mr. Fitzgerald) is about two and a-half millions sterling, the market value being (quoting the same author) five millions sterling. Sir, do you think the Government—that is the public—can be induced to give that sum for what the companies have to offer ?

I think the subject is one of paramount importance to the electrical trade, and I hope that when it reaches the stage of practical politics, you will lend your powerful aid to obtain a thorough discussion, and then with your permission I will again address you.—Yours, &c., JUSTICE.

February 8, 1888.

THE FALSE ZERO METHOD.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : In your issue of the 3rd instant M. Emile Lacoine draws attention to the fact that in using the false zero method in cable testing it is quite unnecessary to keep the resistance of the battery circuit constant.

The truth of this fact, as well as that of the general law of Dr. Frölich, can be very simply shown in the following way :—

Let P R T be a wire through which a current, C, is flowing. The difference of potential between the two points Q and S will be $C r$, if the resistance of the wire from Q to S is r, and if there is no electromotive force between the two points. If, however, between Q and S there be an electromotive force E the difference of potential will be

$$C r - E,$$

and this difference of potential will be zero if we choose the points Q and S so that $C r = E$.

But if Q and S are at the same potential we may join them by a wire without altering the current flowing either in the wire P R T or in any other wire with which it is connected. Moreover, this will be true whatever be the resistance of the wire used to connect Q with S. In particular it will be true even if this wire has no resistance at all. In this case we practically cut out the battery and the resistance r from the rest of the circuit, without changing any current by the process. This means that if we alter the resistance of any conductor, and at the same time insert an electromotive force, the current in that conductor, or that in any other conductor connected with it, will remain exactly the same as before, provided the electromotive force added is equal to that required to maintain the current (formerly flowing through that conductor) through the additional resistance inserted.

A more elaborate proof of this statement will be found given in a paper by me in the *Proceedings* of the Society of Telegraph-Engineers for May, 1887, and reprinted in *The Electrician*, June to July, 1887. Dr. Frölich's general theorem is an immediate consequence.

For if in any network of conductors, such as the Wheatstone bridge, the resistances of the different branches are so arranged that the current flowing in one branch g is un-

Digitized by Google

altered by the insertion of an electromotive force into a second branch b, then the current in the branch g will be unaltered by changing the resistance of the branch b, whether there are other electromotive forces acting in some of the other branches or not. For if we alter the resistance of the branch b by any given amount, we can always find a corresponding electromotive force which, when inserted in the branch b, will produce the same effect in the branch g. If the current in g is independent

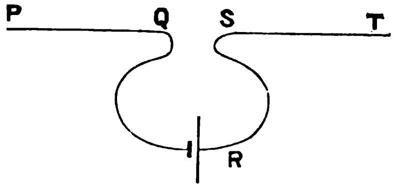

Fig. 1.

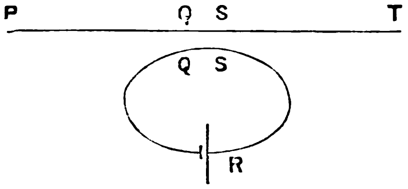

Fig. 2.

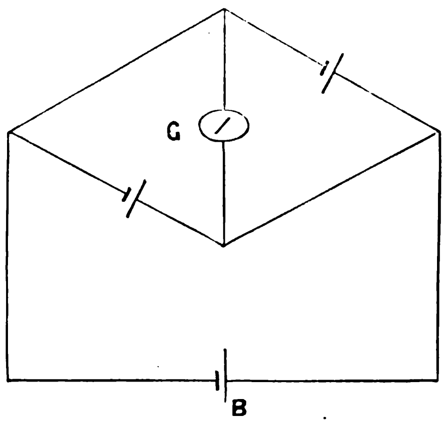

Fig. 3.

of the change of electromotive force in b, it must also be independent of the change of resistance, however great this may be. If, therefore, the current in g is independent of the electromotive force in b, it must be the same whether the battery circuit be open or closed.—Yours, &c.,

W. E. Sumpner.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: On p. 316 of the present volume is a reprint from the *Journal Télégraphique* of an article on the False Zero Method, in which M. Emile Lacoine points out that it is unnecessary to know the value of the resistance of the battery employed in making the test. That this resistance need not be known was shown by the writer in the *Electrical Review* in 1885 (p. 392, Vol. XVII.), and a proof identical with M. Lacoine's was given.—Yours, &c., E. C. Rimington.

[Our correspondent encloses another demonstration obtained by the use of Maxwell's method of cyclic signs.—Ed. *E.*]

SPRINGS ON OVERHEAD WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Mr. Preece appears to overlook the fact that his published Table of Dips and Stresses demonstrates how oblivious he is to the powerful influence of elasticity on the line wires; and his mistake about the effect of springs arises in the same way. I endeavoured to show this in my *unanswered* letters, *The Electrician*, November 4th and December 9th, 1887.

If Mr. Bozon seriously proposes to make less than 1½lb. of india rubber per span compensate the wire at the rate of 4in. yield per ½-cwt. stress, I think he will find he is attempting the impossible. And till he succeeds in this particular further discussion of the remaining features of his invention may stand over.

My springs, which are of No. 8 gauge, are dipped hot in a boiling composition, which renders them about as weather-proof as No. 8 galvanised iron wire.

The value of spring shackles would be specially realised on wilderness lines, such as cross great tracts in Australia and Canada, where the delays of breakdowns and costs of repairs are exceptionally heavy.—Yours, &c., Frank Caws.

Sunderland, February 4th, 1888.

[It is a little amusing to find Mr. Caws instructing Mr. Preece upon the proper method of erecting telegraph wires. Mr. Preece, we take it, has implicitly asserted that the modulus of elasticity may for practical purposes be neglected in calculating the dip of an overhead wire; Mr. Caws asserts the contrary. Mr. Preece also thinks that the service will continue to be carried on efficiently without the aid of Mr. Caws's spring shackles. Our correspondent ventures to differ.—Ed. *E.*]

THE DEFINITION OF THE COEFFICIENT OF SELF-INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In Dr. Fleming's article on "Alternate Currents," p. 315, the electro-magnetic energy of the circuit is expressed by $\frac{1}{2}L i^2$. The expression given in Cumming's "Theory of Electricity," p. 206, is $L i^2$. May I ask if L is different as used in Cumming from its definition in Dr. Fleming's article?—Yours, &c., G. B.

THE EFFECT OF MAGNETISATION ON THE THERMO-ELECTRICAL PROPERTIES OF BISMUTH.

A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Will you kindly correct a slight inaccuracy in the report in *The Electrician* of my paper on the effect of magnetisation on the thermo-electrical properties of bismuth?

Instead of ·0022 microvolt per 1° C., write ·0022 microvolt per unit magnetising force, the temperature of the two junctions being 100° C. and 16° C.—Yours, &c.,

Herbert Tomlinson.

King's College, Strand, February 7th.

BATTERY CARBONS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Can any of your readers inform me what is the relative value and durability of battery carbon plates sawn from the block, and "compressed" carbons? I have an impression that the latter, while being less porous, and more equal in density, are subject to disintegration under the influence of acids.—Yours, &c., Carbo.

TECHNICAL CONFERENCE AT THE ROYAL VICTORIA HALL.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In consequence of the great interest shown in the Conference on Technical Education held here on December 14th, we have arranged another for the 15th inst., at 8 p.m., and Captain Sir Douglas Galton, K.C.B., has kindly consented

Digitized by Google

to take the chair. At the first meeting a resolution in favour of technical education was carried unanimously, and now the subject for discussion is, What is the best way of obtaining it? As before, it is hoped that politics will be avoided, since this is not a party question, but concerns Liberals and Conservatives, employers and workmen equally. All seats will be free, but intending speakers should send in their names to me here *before* the day of meeting. So many expressed a wish to speak during the last meeting that it was impossible to hear all, and it has been thought best to hear those (so far as time will permit) who give notice not later than the previous day. Will you kindly make room for the above particulars in your columns, and oblige,—Yours, &c.,

EMMA CONS,
Hon. Sec. and Trustee.

Waterloo Bridge-road, S.E.,
February, 1888.

LEGAL INTELLIGENCE.

Gaulard and others v. Sir Coutts Lindsay and Co. and Ferranti.

This was an appeal from a decision of Mr. Justice Kekewich. The action was brought by Messrs. L. Gaulard and J. D. Gibbs and the National Company for the Distribution of Electricity by Secondary Generators (Limited) against Sir Coutts Lindsay and Co. (Limited) and Sebastian Ziani de Ferranti to restrain the infringement of five letters patent of the plaintiffs. On the 21st of November Mr. Justice Kekewich, in the matter of a petition presented by Ferranti for revocation of one of the patents, made an order giving the plaintiffs liberty to apply at the Patent Office to amend the specification of that one of the letters patent. The plaintiffs afterwards moved for liberty to apply at the Patent Office to amend the same specification by way of disclaimer, correction, or explanation, and that in the meantime the trial of this action might be postponed, and that the specification, when amended, might be used in evidence at the trial on such terms as the Court might think fit. The application was made under Section 19 of the Patents, Designs, and Trade Marks Act, 1883, which provides that "in an action for an infringement of a patent, and in a proceeding for revocation of a patent, the Court or Judge may at any time order that the patentee shall, subject to such terms as to costs and otherwise as the Court or Judge may impose, be at liberty to apply at the Patent Office for leave to amend his specification by way of disclaimer, and may direct that in the meantime the trial or hearing of the action shall be postponed." Mr. Justice Kekewich was of opinion that it would be unreasonable to allow a postponement of the action as to all the patents. And he said that if the plaintiffs would not accept the defendants' offer, that the plaintiffs should discontinue the action as to the one patent and pay the costs as to that, the motion must be refused with costs. These terms being refused by the applicants' counsel, the motion was accordingly refused with costs. The plaintiffs appealed.

Before the conclusion of the arguments the plaintiffs consented to the order which they asked being made upon the following terms (which the defendants were willing to accept):—That the plaintiffs should pay all the costs of the action up to the present time, and that they should not claim any relief in respect of anything done by the defendants before the amendment of the specification. The defendants to have liberty to amend their defence and particulars of objection.

Lord Justice COTTON said that a long and learned argument had taken place upon the construction of Section 19; but, as both parties had assented to terms, he would give his judgment very shortly. In the case of "Bray v. Gardner" Mr. Justice Stirling had given liberty to the plaintiffs to apply for leave to amend their specification on the terms that the amended specification should not be used in the pending action. The Court of Appeal said that liberty to make such an application ought not to be given under Section 19, unless it could be given without injustice to the defendant. But the Court did not say that the terms then imposed ought to be imposed in every case. In the present case Mr. Justice Kekewich thought the other terms should be imposed. But the appellants had now offered terms which his Lordship thought would do complete justice in the present case. This offer had not been made in the Court below. As the plaintiffs were asking for an indulgence, they must pay the costs of this application in both courts.

Lord Justice LINDLEY agreed. He did not think there was any difference between "Bray *v.* Gardner" and "Allen *v.* Doulton." In every case the Court must see what would be right and just.

Lord Justice BOWEN also concurred. He desired to point out that what had been said by Lord Justice Cotton in no way narrowed the construction of the Act. When an Act of Parliament had vested a discretion in the Court, the Court never wished to limit that discretion by laying down rules as to the way in which it was to be exercised. The discretion was given to the Court. The language of Section 19 appeared to indicate that terms were to be imposed by the Court, if it should think the justice of the case required that they should be—that is, in order to prevent injustice being done to the one party by the indulgence which was granted to the other. That was exactly what was laid down in "Bray *v.* Gardner."

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

1,243. H. LUCAS and E. D. VAUGHTON. Birmingham. An improved portable electric lamp. January 27, 1888.

1,250. M. IMMISCH. London. An improved water-wheel for driving electric generators and its combination with, or application to, such generators. January 27, 1888.

1,254. J. SPINK and C. GAUZENTES. Bradford. Improvements in forming metallic connections with incandescent lamps and holders therefor. January 27, 1888.

1,364. F. J. MARTIN. London. Electric lighting for railway and other carriages. January 30, 1888.

1,383. F. BOREL and E. PACCAUD. London. Electric apparatus for use either as an electro-motor or as an electric current meter. January 30, 1888.

1,386. G. FOWLER. Peckham. Improvements in telegraph insulators and appliances for suspending wires on aerial telegraphs. January 30, 1888.

1,406. M. TURTON and S. TURTON. Tipton. Improvements to and in connection with electric time signals or alarums. January 31, 1888.

1,461. R. K. BOYLE. London. Improvements in applying metals to metals by electric action or electric fusion, applicable more especially to obtaining a rough hard surface or a surface of a character other than that of the metal to which the said surface is applied, but applicable in other cases where metals can be joined to metals by electric action or electric fusion. January 31, 1888.

1,505. M. McMULLIN. London. Improvements in the construction of electric brushes for curative purposes. February 1, 1888.

1,525. L. E. SOLIGNAC. London. Improvements relating to the distribution of electricity. February 1, 1888.

1,536. J. BATTYE. Batley. Magnetic and electric telephone and telegraph for transmitting and receiving musical vibrations or signals by means of electricity. February 2, 1888.

1,557. F. JACOB. London. Improvements in the duplex telegraphy. February 2, 1888.

COMPLETE SPECIFICATIONS ACCEPTED.

NOTE.—*All persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the dates in italics, give notice at the Patent Office in the prescribed form of such opposition.*

February 4, 1888.

3,658. R. DICK and R. KENNEDY. Glasgow. Improvements in alternating current transformers or induction coils. March 10, 1887.

3,767. J. LEA. London. A method of checking or arresting the feed of an arc lamp and appliances for the purpose. March 12, 1887.

4,070. M. H. P. R. SANKEY and P. W. WILLANS. London. Improvements in combined engines and dynamos. March 17, 1887.

4,781. THE ELECTRICAL POWER STORAGE COMPANY (Limited) and H. W. BUTLER. London. Improvements in electric batteries. March 30, 1887.

4,809. E. TORTORA. London. Improvements in insulating electric conductors. March 31, 1887.

17,837. P. M. JUSTICE. London. Improved means of generating electricity from heat (E. G. Acheson, United States). December 28, 1887.

17,888. G. A. SMITH. London. Improvements in and relating to electro-magnetic marine governors. December 29, 1887.

17,965. F. REDMOND. Dublin. Improved machines for cleaning windows, mirrors, and similar articles, by either mechanical or electrical power. December 31, 1887.

PATENTS SEALED.

January 27, 1888.

1,738. C. D. ABEL. London. Improvements in dynamo-electric machines (Siemens and Halske, Germany). February 3, 1887.

13,091. M. VIAU. Bilbao, Spain. Electric motor for clocks and for industrial purposes requiring small power. September 27, 1887.

January 31, 1888.

275. R. E. B. CROMPTON and J. F. H. SOLL. Chelmsford. Improvements in and apparatus for effecting the distribution of currents of electricity. January 7, 1887.

1,331. D. HALPIN and J. A. TIMMIS. London. Improvements in commutator brushes or contact pieces for electrical apparatus. January 27, 1887.

COMPANIES' MEETINGS.

Anglo-American Telegraph Company (Limited).

The Right Hon. Viscount Monck presided at Winchester House, Old Broad-street, over the half-yearly general meeting of this Company, which was held on the 3rd inst.

The SECRETARY (Mr. T. H. Wells) read the notice convening the meeting and the minutes of the last meeting, and the report of the Directors was taken as read.

The CHAIRMAN: It is now my duty to move the adoption of the report, and in doing so to give you a short epitome of the history of the Company for the last six months. The first observation I shall make is that during the past six months we have carried a very large increase of traffic, as you will see by referring to the report; but I regret to say that it is not satisfactory in one sense—that it has not yet become remunerative. With regard to the expenses there is very little to be said. You will find on referring to the statement that the expenses are pretty much what they were in the corresponding half of last year. There are one or two items that are in excess, but they may be accounted for by special circumstances. One is the expense of stationery at the stations, and that increase is caused by a very large supply sent out to Heart's Content, Newfoundland. Another item which is a little in excess is that of travelling, which was caused by moving clerks from station to station at the time the 1869 cable was not operating. There is also an item for lodging allowance, fuel, light, and provisions, which is in excess of last year. I am sorry to say that that is caused by our having to provide extra provisions for Newfoundland and the smaller stations, owing to the loss of a cargo by shipwreck. There is also an item of repairs and furniture, which exceeds that for last year, due to special repairs at the Heart's Content Station, amounting to £1,200. These are the only things which I refer to in the working expenses, but we have had a very considerable addition to our general expenses this half year by the repair of the 1869 cable, and also for transferring the shore ends of cables at Valentia Bay. The repair of the 1869 cable appears to me to be a most important circumstance—in fact, I think it almost marks an epoch in the history of telegraph construction and repairs. You must remember that the 1869 cable was laid down, as its name implies, in the year 1869, so that it was eighteen years under water when it was lifted. The breach was in 2,750 fathoms; but it was lifted in 2,300 fathoms. It was lifted by our own ship, and I do not think that we ought to discuss this matter without paying a tribute to the very great ability, energy, and skill exhibited by Captain Trott and the officers and crew of the steamship "Minia" (cheers). I think it is only fair that the meeting, in discussing this matter, should remember how much you owe to the intelligence and energy of those people. Well, gentlemen, we had also—not a repair exactly—but we had to transfer the shore ends of the cables at Valentia from their original positions, in which they were subject to abrasion from the roughness of the bottom on which they were laid, to another position, in which there was a sandy bottom, and in which they rest more easily, and with less risk of injury. Now, this 1869 cable has been several times under repair, and the other day I was talking to my friend, Mr. Weaver, about it, and I said, "It seems to me it must by this time be like the proverbial schoolboy's knife, which first had new blades in place of the old ones, and then a new handle, so that there was no part of the original knife left." Mr. Weaver, however, corrected me by having a diagram made, which I should very much like to exhibit to you, for I think it would be as interesting to you as it was to me. It is a diagram of the bottom of the Atlantic, showing the way in which this cable lies. The bottom of the Atlantic in its configuration is not very different from the surface of the earth. It has its valleys and hills, and its mountains and plains, and you will find, on looking at the diagram, that the injuries to the cable have been produced in only two or three places over the whole space between here and America, and that for a very large portion of the distance the cable has lain perfectly secure, because it lies on a soft and smooth bottom. Where it hangs down from mountains—and 2,750 fathoms means a very high mountain, indeed three miles high—where it hangs down from such places as that it is subject to constant injury, and it is in those places that the injuries have taken place. In the very long part which exists between those rough portions of the distance the cable is perfectly secure, and has for nearly nineteen years never been injured. I think, as far as Atlantic cables are concerned, there is some consolation in this matter, for it shows that if we only can get a good bottom we may calculate on a very long life for our cables. (The diagram was here placed on the wall and explained to the meeting.) The Chairman continued: I thought it would be interesting to you to show the exact position of the cable, and I asked Mr. Weaver to bring the diagram here. The faults were removed by Captain Trott, of the steamship "Minia," most effectually, and the traffic through the cable was restored. I am sorry to say, however—as you will see by the report—that it has given out in another position, somewhat in the same direction as the former one, but a little nearer to Europe. In addition to our contest with Nature, so to speak, at the bottom of the sea, we have had a contest with the French Company, as you are aware, in the law courts in Paris. They, as we contend, acted contrary to their agreement, and left what we call the pool of the associated companies, and attempted either to set up for themselves or to join our opponents. We brought our action against them for doing so, and we have succeeded so far that we have obtained a decree entirely in our favour, and until that decree is reversed we have a right to suppose that we are on the right side. An appeal has been notified and will take place in a short time, and until that appeal takes place of course we cannot consider ourselves out of difficulty, and we must wait until the decision of the Court on the subject is given. These are the matters which I call the history of the Company during the six months. I now come to what is a matter of much more importance, and that is the contest which is going on between us and the Commercial Cable Company. We have been accused of having what is called a fighting tariff. Now, I should like for one moment to refer back to the beginning of the contest to show that if there is any moral turpitude in instituting a fighting tariff we are not the parties who should be accused of the crime. I may say, at the same time, that the accusation sits very lightly on my shoulders. However, as a matter of fact, when the Commercial Company commenced their operations the tariff was 2s. a word. They reduced their tariff to 1s. 8d., and of course we were obliged to come to the same figure. We have not the same power over the public that the Commercial Company seem to have. We cannot get people to give 2s. for what they can buy for 1s. 8d., although the Commercial Company managed for some time to get 1s. for what the public could get from us for 6d. That was the state of things a year and a-half ago, and your Board, on considering with great care all the circumstances of the case, came to the conclusion that the only policy that we could adopt was to reduce the tariff, not for the purpose of fighting, but for the purpose of stimulating the traffic with the object of gaining a large revenue from a low tariff. That object was fully stated here by me at the time. It was accepted by the great body of the shareholders as a wise and proper policy to adopt, and I am still of the same opinion. At the same time, if you will remember, I carefully guarded myself against naming sixpence, or any sum, as the ultimate point at which the tariff should be fixed. I told you that we were engaged on an experiment; that our design was to attain two objects—one, to adopt a low tariff, to increase the traffic and stimulate consumption by means of the reduced price, and the other to ascertain what tariff would give us a fair revenue, and not so large a revenue as to encourage further competition. We stated, at the same time, that we would give the sixpenny tariff a fair and full trial; that we would make no alterations until we had ascertained how far the sixpenny tariff would answer the objects that we had in view. I told you at the time that the policy we had adopted, and which you approved, would make a considerable demand upon your patience and forbearance, and I ventured to predict also that it would largely increase the traffic over the cables. My vaticinations in both respects have been fulfilled—in one respect I am afraid absolutely; in the other, only partially. I am afraid your patience has been sorely tried, and I am sure no one in the world regrets the necessity for it more than my colleagues and myself. The other prophecy which I ventured to make—that the traffic would be largely increased—has also been fulfilled. You will see by the report that our traffic at present is 162 per cent. larger than it was before the sixpenny rate was adopted; but, unfortunately, that is not enough to give you a remunerative revenue. I think we have given the sixpenny tariff a very fair trial. For the first year the increase was very large, but for the last year it has been only 12 per cent. Although that 12 per cent. might, in a certain time, grow to a very much larger amount, I am afraid that the trial of your patience would be so great that it would reach what is called "the straining point," and that we should not be able to do it. I think we have tried the 6d. tariff to its full extent, and I do not think there is that element of increase in the traffic which promises to render it remunerative to the shareholders. But the question is—What are we to do? We have had meetings with representatives of the Commercial Cable Company, which have led to nothing except demands on their part to which it was impossible we could subscribe. My friend, Sir John Pender, at the Direct meeting the other day, threw out a hint that we ought to have a conference. Well, I can only say I am entirely at one with Sir John Pender, and so is our Board, that if anything can come out of a conference we are most anxious to hold it. We are quite willing to go into another conference, and to hear what is said by the other side, and to say what we have to say; but I confess that my experience of the past has not been such as to render me very sanguine as to the result of what the conference might bring. However, I am always willing to let hope triumph over experience, and if Sir John Pender can induce the other parties interested in the matter to come into a conference he will not find us holding back; and I may say, on the part of myself and colleagues, that we will go into a conference with perfectly unbiassed minds, and if it is held we are prepared to carry on any further experimental investigations as to the amount of tariff which may be proposed, and if any proposals are made which seem to us likely to lead to satisfactory and just conclusions they will not find the Anglo-American Company an obstacle to their adoption. Gentlemen, with these observations, I beg leave to move:

"*That the report of the Directors and accompanying statement of accounts*

Digitized by Google

"to 31st December, 1887, submitted to this meeting, be and the same are "hereby received and adopted." (Applause.)

The Most Hon. the Marquis of TWEEDDALE seconded the motion.

Mr. THOS. SMITH (York) supported the adoption of the report, which he thought was a moderately satisfactory one, showing an increase of 162 per cent. of traffic compared with the same period of 1885, and over 1886 of 12 per cent. That had enabled the Directors to pay 10s. per cent. on the ordinary stock and 20s. per cent. on the preferred shares for the last quarter, and to carry forward a balance of £2,344. For the same quarter of 1886 there was no dividend, and no balance was carried forward. Therefore, he considered the present report so far satisfactory that they were enabled to pay the dividend mentioned. The sixpenny tariff had now had a fair trial, having been in operation nearly two years. They could not, therefore, reasonably expect after the experience they had had that there would be a much larger increase. There might be a little better traffic or a little worse, but to his mind the sixpenny rate was now about played out. The question therefore which the shareholders had to face was whether the dividend at the present rate of 2 per cent. per annum—supposing they were able to continue it, and he thought they would—was a sufficiently remunerative one to satisfy the shareholders. Without wishing in any way to hamper the Directors, he would suggest that now was a time to consider and settle a further reduction of the rates. That was the policy which he had advocated from the commencement. He was still of the same opinion as before, and he thought it was worth the attention of the Board, though he did not wish to tie the Board to any decision. In paragraph No. 7, it is notified that the Western Union Company since the last meeting had opened negotiations with the Commercial Company for an amicable settlement. He was sorry to say that the Commercial Company's demands were of such a nature as to prevent any agreement being arrived at, and they threatened that unless their terms were agreed to they would immediately adopt a 6d. rate. They had been previously charging 1s. He was pleased to say that that threat had had no effect on the Directors. It was no use trying to hide the truth from themselves—that both companies fully understood that they were engaged in a war in which one must give way. It was pretty well known that the Commercial Company at the present time were making no dividend, if even they were paying their expenses. The Anglo shareholders had submitted for some time very patiently to receive very small dividends. He thought they might reasonably say that they had now come to a crisis in their affairs, and that one party must give way. They must have war, and they must face it as a war, and he thought that a 3d. rate would terminate that war. There was no doubt that the Commercial Company had used the French cable as a very strong weapon against the Anglo Company. He thought the Directors should carry out the policy which they had been compelled to adopt in sheer self-defence to its logical conclusion. The Company formerly charged 2s. a word; the Commercial Company reduced theirs to 1s. 8d., and he believed that that company had some other policy which the Anglo shareholders were not aware of. It was no use burking matters. Some shareholders would say: "Let us have peace—peace at any price. We want a 1s. or 1s. 6d. rate. Never mind other parties; let us attend to our own affairs." He held, however, that if they adopted such a policy as that they would eventually be in a worse position than they were in now. While referring to the action of their opponents he congratulated the Board on the victory which they had gained over the French Company in the law suit. He thought they ought to congratulate the Directors, and especially the solicitor, on the manner in which the agreement was drawn up between the Company and the French Company. If it had not been well done, and done in a lawyer-like manner, probably the agreement would have been evaded. He believed the Directors would continue to carry their point. Paragraph 4 of the Directors' report was worthy of the shareholders' attention, for he believed that it marked great progress in the power of effecting repairs in cables at almost any depth. That fact meant that they would need no further increase to their renewal fund. He thought that that fund was now shown in such a way that it must be satisfactory to the shareholders. It showed at a glance the par value of the investments, the cost and the annual interest from each investment. The market value that day of their renewal fund was only £6,000 short of one million. He thought that was a very favourable item in their balance-sheet. The whole amount invested just returned an average of 3½ per cent., which in these times indicated a splendid investment, especially where they had security, as was their case. Their financial position was therefore a strong and sound one.

Mr. CHESTER said he noticed that their dividend that day entirely depended on an estimated balance brought forward. The auditors in auditing the accounts had carefully taken a position in which their audit was based upon that estimated balance being correct. He would be glad if the Directors could throw a little light on those estimates now. With respect to the lawsuit just concluded, he would also wish to ask whether the company which appealed against the decision that had been given had not questioned the validity of the Court which had given the decree lately received by the Company. With regard to the 6d. rate, he was rather surprised to hear a gentleman advocating such a rate to-day. That rate was brought forward as a fighting rate. The Chairman told them so at the time.

The CHAIRMAN: No, no!

Mr. CHESTER said he would not contradict the noble Chairman. He, however, protested against it at the time. He did not wish to be guilty of egotism, but he thought he might say that the remarks which he made at the time had turned out literally true. He was very sorry to hear proposals made to reduce the rate to 3d. a word, and he would ask the shareholders to remember that they were now only travelling over the same proceedings which had marked the history of the Company for the last 15 years. He asked them had those proceedings ever resulted in any benefit to the shareholders? They tried to crush out opposition, and what had that led to but to other cables being laid? Did they think that they could say to the world that the traffic across the Atlantic was their own, and that they were determined to oppose every company tooth and nail that opposed them? If they said so he thought they formed a very wrong estimate of the rest of the world. They were just repeating what they had done before, and he asked them whether they would not have the same results as they had before? He would have been very much pleased to hear a proposal to come to some intermediate arrangement. He thought it would pay them better if the rate were raised to something like 9d. a word, which would pay the Company and meet the wants—the growing wants—of the community. A year or so back he told the shareholders that the gentleman who had just preceded him had represented the deferred shareholders to a great extent. He (the speaker) wished to ask the ordinary and the preferred shareholders what their interests were? They were the base of the Company. The deferred shareholders had only a right after the other shareholders were satisfied. He considered that they were in a grand position now with a fund of a million invested, which had been taken out of the pockets of the ordinary and preferred shareholders. A few years ago, when they were in a state of depression—he was glad they were getting out of that condition now—there were movements with a view of getting alterations in the Articles of Association, more especially with respect to the voting power. The deferred shareholders of the Company had equal voting power with the other shareholders. There was thus, on any question that might arise, £2,700,000 of voting power in the hands of those who he, maintained, were very little interested, and thus there was a power of swamping the shareholders with the votes of the deferred shareholders.

A SHAREHOLDER: The deferred shareholders have no voting power.

Mr. CHESTER said he believed his statement to be correct.

Mr. WOOD said he had been thinking whether they could not adopt another policy as regarded the rates—whether they could not have two classes of rates: one a 9d. rate for express messages, and another a 6d. rate for ordinary messages, so that those who required their messages to go instanter would have to pay an extra 3d. a word, and those who were not particular to an hour or two would pay a 6d. rate, and their messages would be transmitted in a short time. He thought it would be a mistake to alter the 6d. rate otherwise. The public did not like the constant chopping and changing of the rates. There was great irritation in the public mind against the Company. He thought it would be a good thing of them to maintain the 6d. rate, for he was sure that it would be the rate of the future. If the course he had suggested could be adopted they would possibly tide over the present crisis, and as the traffic was growing—last half-year it increased 12 per cent.—and as trade improved, of which there were signs on all sides, they would have a further increase of traffic, and they would find in the end that the 6d. rate was paying them.

Mr. JOHN NEWTON said that he did not exactly understand the speech of Mr. Chester. It seemed to the speaker that there had been nothing but a "squaring" of the opponents of the Company, and that as frequently as they compromised with their opponents they would bring about another competing cable. Any arrangement they made with their competitors would be subject, he should say, to some kind of "pool," and once they had a pool between England and America the monopoly to which reference had been made was created at once; and they could not avoid a monopoly, do what they would, in the carrying of messages between the two countries. It was inevitable. He disagreed from the Chairman about the present not being a fighting rate. There was no doubt that it was a fighting rate. They could not help themselves; they must fight with their competitors. The Bennett cable was a competing cable, and therefore the rate now in force was a fighting rate. He hoped that when an arrangement was made with the Bennett people it would be on the Anglo Company's own terms. When the original French Company had to be dealt with there was the "squaring" process. Then the Direct cable was started because its makers knew that the Company would buy them up, and they did so (No, no). Well, they were "squared." Then, when that was done, the cable contractors said: "Here is a market for another cable and we will lay it, and other companies will then come forward." As the result of that the French Company had to be taken into the "pool." It was inevitable that they would come to some arrangement with the Commercial Company, and then the telegraph engineers would lay another cable, and they would have to buy that unless they adopted the policy of downright fighting rates and buy the new cables that were laid at less than they cost the original makers. When they had beaten such opposition they could charge a rate that would be commercially sound, not one to pay handsome profits to the shareholders, though he did not say that they were not entitled to a good return. He maintained that there was no enterprise that more deserved a continual permanent 10 per cent. dividend, considering the grand work which they had done, but until they had thoroughly beaten their opponents by buying up the cables at less than they cost the contractors, they would have cables laid. In these days of commercial enterprise, if a market could only be found for goods, the goods would be produced, and a market had been found for the goods produced by cable-laying companies.

Mr. JACKSON said he rose not to oppose the report, but as a shareholder to complain, and he thought the circumstances justified complaint. The shareholders' patience had been exhausted. Certainly his had. He did not think the meeting was acquainted, notwithstanding what Mr. Smith and Mr. Newton had said, with what had been the cost in the last two years in money of the war of rates. The result to the shareholders had been that for the last two years—which some speakers seemed to regard as satisfactory—they had had a return on their capital of 16s. 3d. per cent. per annum. After twenty-two years' management of the Company by the most experienced men, and men of the highest position in the commercial world, he maintained that that was a result which justified great

Digitized by Google

impatience, and was one which the shareholders should not tamely sit under. He did not think any shareholder in the Company would say that for the splendid services rendered by the Atlantic telegraph cables a 5 per cent. dividend was an excessive one. Mr. Newton had said that they ought to have a 10 per cent. guarantee. For his own part he held that 5 per cent. was not an excessive, but was only a moderate, return, though it should be considered a satisfactory one. Such a return as that in the last two years would have put into the shareholders' pockets £500,000 more. Were the shareholders satisfied with what they had received? If so, he had nothing further to say; but he was not satisfied. He considered it a most miserable result. If they had put their money into the funds they could have taken it out at a premium, whereas, having put their money into this Company, if they sold they would have to take 60 per cent. discount. The Chairman had told them that he was perfectly prepared to go into a conference to see what could be arranged, and no doubt shareholders could thoroughly trust themselves in a conference in the hands of their Chairman, Sir John Pender, and other gentlemen. They would be perfectly safe in the hands of those gentlemen, and they would find that their interests would be most thoroughly safeguarded. He thought that that was the most satisfactory announcement which had been made by his lordship. The shareholders knew what a war of rates was. Mr. Newton had told them that in this centre of commercial civilisation they must have a monopoly in their business, but he (Mr. Jackson) considered such an idea as that absurd. The bottom of the Atlantic was no man's territory. It was infatuation to demand what Mr. Newton had asked for. Mr. Newton had said that they must crush opposition. Did they think they could crush Mr. Mackay? As the result of the policy which they had adopted, the return which they had had for the last half-year had been only ⅞ per cent. He thanked the Board for one thing—their renewal fund; but looking at the return which the shareholders had received, he maintained that it was a humiliating position for the Company to be in after 22 years' working. He had been glad to hear the remarks that had been made respecting Captain Trott, whose repair of the 1869 cable would put more backbone into the position of the Company than anything else. The work performed by Capt. Trott had raised the value of Atlantic Cable property considerably, showing as it did that they did not want such an enormous renewal fund as was possessed by the Company. In the beggarly position of the Company, with their ⅞ per cent. return, he dare not propose any pecuniary reward to Capt. Trott, but he would propose that a hearty vote of thanks should be awarded to that gentleman.

Mr. Newton desired to explain that he had not in anything he had said assumed that they could crush Mr. Mackay. That gentleman was a man of business, and he asked the Directors to deal with him from that point of view. As to crushing him they could not do so.

Mr. Humphries thought the Chairman had placed before the shareholders the position of the Company in too roseate a colour. He found that instead of their having made any dividend last year they had a deficiency of £5,400. If they had had no reserve fund there would have been no dividend at all, seeing that their expenses last half-year exceeded the receipts by the amount he had mentioned. He thought that ought to convince the Directors that instead of a fighting policy they ought to try a policy of conciliation with their opponents, who were, perhaps, as much determined to fight as the Company were. For two years they had been going on at a continual loss, and he now thought they should try conciliation. He was not in favour of advancing the rates too high. They had tried a 6d. rate, which did not pay; let them now try 8d., 10d., or 1s., or such a rate as would not induce parties to lay another cable. With regard to the remarks which had been made about the deferred shareholders, he thought those holders ought to be considered. He supported the idea of the conference.

Mr. Seely said that within his recollection the Brest-St. Pierre cable had been repaired a great many times—at least six or seven times within the last seven years. If that were the case would the Chairman kindly inform them what the actual cost had been during the last seven years of those repairs, because if they were to go on repairing the cable it would be like what the Chairman had referred to as to the schoolboy's knife, and it might be more economical to have a new cable entirely, instead of going on making repairs. As to the policy of continuing the 6d. rate, he endorsed what the Chairman had said about being willing to go into some conference with their opponents. He thought the time had arrived when the 6d. war rate should end, for the small dividend which they had been receiving for the last two years was, as Mr. Jackson had said, deplorable.

A Stockholder desired to have an explanation of the item of £1,078 for repairs, furniture, &c., in the expenses at stations.

The Chairman said that probably he had not expressed himself clearly before. There were special repairs at Heart's Content station last year which took the sum of £1,200 out of the £1,780. That would not occur again.

A Shareholder observed that in paragraph 8 it was stated that the traffic in the past half-year showed an increase of 12 per cent. over that of the corresponding period of 1886. In the preceding paragraph it was stated that the Commercial Company had reduced their charge to 6d. He thought, in comparing the corresponding period with last half-year, they were not comparing the same things, for in the earlier period the Commercial Company were charging more than they were charging in the later period. He wished to know whether the increase from the 1st July to the 15th Sept. was at a greater rate than later on.

The Chairman: It is very difficult to answer that question. We have no means of knowing, except by estimating the proportions of traffic carried by the Commercial Company, and therefore it is very difficult indeed to arrive at a just and accurate conclusion as to the increase that has taken place between any two periods.

The Shareholder: I mean what was the increase of our traffic from the 1st July to 15th Sept.?

The Chairman: I could not answer the question offhand, but we could at the office, where you shall have the answer. Mr. Chester referred to the question of estimated balances. That phrase has been introduced, and necessarily introduced, into the report because our net balance will depend on the decision of the lawsuit in France. We have already had a decision in our favour which gives us a gross sum of about £30,000, or 2,000 francs a day for every day that the French Company adhere to their resolution to abandon the pool. But until that question is finally decided by the Court of Appeal everything we do must be mere estimate. Mr. Chester also asked me if the French Company were going to object to the competency of the Court that has already given this decision. I presume the French Company, if they are well advised, will take every objection they can to the decision; but I am not in their counsels. Mr. Burt, the solicitor, tells me that they did not raise that question in the tribunal before which we have gone. I cannot tell whether they will raise it now. I am very unwilling to trouble the meeting with what appears to be a mere personal question, but Mr. Chester insists that we adopted the 6d. rate as a fighting rate. Now I will read what I said in July, 1886, on the adoption of that rate. Having read extracts from the speech in question and from that which he delivered last year, he continued: I have thus kept this rate in every case distinct from the expression "a fighting rate." Mr. Wood suggested express messages. Mr. Wood cannot have a large experience of these meetings, or he would not have come forward with that suggestion as an original idea. I scarcely remember a meeting for the last ten or twelve years in which the same suggestion has not been made, and I have been obliged always to make the same answer—that the law will not allow us. Mr. Wood also said that there were continual choppings and changings of the rates. Well, all I can say is that we have had the 6d. rate in existence for nearly two years, and if we found it satisfactory we should not have the least wish to change it. The next observation I wish to make is with respect to what was said by Mr. Jackson, who expressed himself—and certainly his manner and tone entirely justified what he said—to the effect that he was thoroughly impatient; and indeed allow me to say that I am not in the least surprised at it. But, on the other hand, he may be impatient with the result without being impatient with the management of the Company. If you find that we are only fighting against facts which cannot be changed, and that we have done our best in dealing with these facts, I think that whatever your impatience may be with the results you should give us the credit of having done all that we could for you. Mr. Jackson, at the same time, did us the honour to call us men of experience and high character, and he also said that if we go into this conference, the shareholders will be quite safe in the hands of myself and Sir John Pender. I am very much obliged to Mr. Jackson for his good opinion of myself and Sir John Pender; but I think that it is inconsistent with what he has said as to the way in which we have managed your affairs. In point of fact, if the state of affairs is as humiliating as he says, he ought to turn us out. I do not think we deserve the character of experienced and good business men if this present state of things is due entirely to the Directors. I think we have done our best to meet facts which we could not control. Mr. Humphries said that if the repairs had been paid for out of revenue we could have paid no dividend. That is so; but the renewal fund was created for that very purpose, and it was by paying for the repairs out of renewal fund, which some gentlemen are very fond of clamouring against, that we were able to pay any dividend this time at all. Mr. Seely asked the cost of repairing the 1869 cable. That cable, as I said before, was not exactly in the condition I at first thought it was when I used the illustration about the schoolboy's knife. We have spent a great deal of money on that cable, but I cannot give you the figures of the cost offhand. Roughly, however, Mr. Weaver says, it has cost about £200,000, and is a long way short of a new cable. If it was for nothing else I think it is worth repairing and keeping it going as a test of how long a cable will last effectively in the Atlantic. It will have been down 20 years next year, and we have hopes and expectations that for a comparatively trifling cost we shall repair the present breach in it and it may remain intact for years to come. There is one consideration which we should not lose sight of, namely, that the other cables which have been laid down subsequently to this cable are of much better construction and likely to last much longer. He then put the resolution in the usual way, and declared it carried unanimously.

On the motion of the Chairman, seconded by the Marquis of Tweeddale, Sir Daniel Gooch, Bart., was re-elected a Director of the Company, as was also Mr. F. A. Bevan, on the motion of the Chairman, seconded by Sir James Anderson.

Mr. Davison then moved and Mr. Jackson seconded the re-election of the auditors, Mr. Joshua Dean and Mr. Francis Glass.

Mr. Jackson then proposed the following resolution:—

"*That the best thanks of this meeting of Anglo-American Telegraph stock-*" "*holders be given to Captain Trott and the officers and crew of the ss.*" "*'Minia' for their able and most successful services in repairing the*" "*Company's Brest-St. Pierre Cable in September last at the great depth*" "*of 2,300 fathoms.*"

He wished only to add with regard to the Chairman's observations respecting his (the speaker's) impatience, that the shareholders could judge only by results.

Mr. Stockdale seconded the motion.

The Chairman: I entirely concur in this resolution.

He then put it to the meeting, and it was carried *nem. con.*

Mr. Fry moved a vote of thanks to the Chairman and Directors, and expressed a hope that the Board would maintain a sixpenny tariff, in which case he believed that in the future they would have a very different tale to tell.

Mr. Smith seconded the motion, which was carried unanimously.

The Chairman: I am exceedingly obliged to you for your kind resolution. I have had the same demonstration of confidence so often that I

Digitized by Google

find it difficult to discover a change of words to express my thanks. I am sure my colleagues entertain the same feeling.

The proceedings then terminated.

The Cuba Submarine Telegraph Company (Limited).

The thirty-third ordinary general meeting of this Company was held on Wednesday at the offices, 61, Old Broad-street, Mr. Joaquin de Mancha in the chair.

Mr. JAMES SCOTT (the Secretary) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said : The next thing that I have to propose is that the report and accounts now submitted be received and adopted. It is my good fortune again, gentlemen, to come before you with a very good return. I think we must congratulate ourselves upon the progress of the Company, and the success which the report we present you here so fully conveys to all who have taken the trouble to read it—I am afraid some of those present have not read it—but at all events the report and accounts are so clear that they do not require much explanation. You will see that our messages, compared with December, 1886, have increased in number 1,528, and in amount £1,523. The expenses are much about the same, although the repairs show an increase of about £300, which you will see from the report is in consequence of the harbour length having been worn out and replaced by Mr. Keith. There has been also a store built for putting in the spare cable which we have there, which Mr. Keith thought was necessary for the better preservation of the cable. You will see, gentlemen, that we are able to pay the half annual payment for the cable which we have contracted for, which amounts to £1,875 ; and, besides, we have in hand sufficient to pay to the preference shareholders the 10 per cent. to which they are entitled, and we also propose a dividend at the rate of 8 per cent. per annum upon the ordinary shares. I think that that is so satisfactory that it requires no comment. I have now to move that the report and accounts be received and adopted.

Mr. ALEXANDER F. LOW : I beg to second that.

The CHAIRMAN : If any gentleman wishes any explanation I shall be very happy to give it.

Mr. COCHRAN : I should just like to ask a question—how long the payment for the cable stands over ? It appears to me we are laying by an excessive amount. I have great faith in a reserve, but when you take into account we have £1,800 for this cable, that we have practically done all our repairs out of revenue, that we are laying aside this half year £3,000, it seems to me rathar an excessive amount. That is the policy the Directors are entitled to adopt and a safe policy, but it is a large sum in relation to the revenue which the shareholders are receiving. I notice there is a slight increase, if I am not mistaken, in the capital expenditure, which strikes one as a little singular, considering that the expenses are considerable, and that we are paying for repairs out of revenue.

Mr. M'LAREN SMITH : How is that cable getting on which you gave us rather an ominous account of at the last meeting ?

The CHAIRMAN : I think we have mentioned before, gentlemen, that we made a contract for this cable, for which we were to pay £48,000 ; instead of purchasing it at the time we made the contract to pay every year £3 750. We have paid up to now about £28,000, and there is still about £19,000 to pay, when the cable will become ours. We thought it was desirable at the time, and I think it has been a very good thing for the Company, instead of running the risk of buying a cable, and it perhaps not answering our purpose, to make the contract which we did. We have still five more years to pay, and the contractor agrees to keep a certain sum of money in our possession in case the cable requires to be put in repair. We have £5,000 for this purpose. Up to the present time it has worked most creditably to the Messrs. Hooper. At the time we were rather afraid it would not, but it has worked most satisfactorily, and we have great pleasure in being able to say so. With regard to the increase of capital, there has been, as I have already mentioned, an additional store built for the reception of spare cable; that cost £715 and has been charged to capital account. It is a good job done, and Mr. Keith said it was necessary we should do it. About the Batabano cable, I am sorry to say after the report was printed we had a telegram from Mr. Keith to say that the cable had not spoken. He had found out where the fault is, and he believes it will not be a very expensive job to repair it.

Mr. KEENLYSIDE : I really think you are piling up your reserves a little beyond the means of the Company. Would it not be possible to agree with Mr. Hooper to pay off the rest of his debt out of the reserve fund, instead of letting it go on for the next five years ? Could you not make some sort of bargain by which we should be in receipt of that revenue? It seems rather exorbitant to go on adding £6,500 to the reserve fund. It is 4 per cent. on the capital ; we are earning 12 per cent., and we are getting 8 per cent.

The CHAIRMAN : Half of the amount that we put to the reserve fund is from the interest produced by it, therefore it is not such a heavy charge as you think. It earns its own living, as you may say. As to the idea of paying for the cable, I like to have money to pay my debts, but I think it is better in my pocket than my creditors'. If I have a bill to pay three months hence I do not hasten to pay it until the money is due. The money is better in our hands than the contractor's, and, though we have no reason to believe that the cable will break, while we have the money in hand we have that extra security. If we pay for the cable at once that security wou'd be gone. We should have paid the money, and if the cable went wrong we would have to repair it ourselves. The moment the cable did not speak we should tell Mr. Hooper to go and repair it. We have £5,000 in hand for that ; we pay according to the contract that was made at the time, and I think it is for the benefit of the shareholders to continue the existing arrangement.

The motion for the adoption of the report and accounts was then put, and carried unanimously.

A dividend of 10 per cent. on the preference shares, subject to income-tax, was declared, and of 8 per cent., free of income-tax, on the ordinary shares, payable on and after the 9th inst.

Mr. HOOPER said the Government Store Department sent out a short time ago a cirular advertising short pieces of cable core that they had for disposal. These came into his hands, and proved to be some of the core his father supplied twenty years ago for the Indo-European Government. He had several pieces tested, and the insulation proved to be as good as at first. He was quite sure that it would be satisfactory to the shareholders to know that.

A vote of thanks to the Chairman and Directors then terminated the proceedings.

Submarine Telegraph Company.

Report of the Directors to be submitted at the meeting of the proprietors, to be held at the offices of the Company, 2, Throgmorton-avenue, London-wall, E.C., on Tuesday, the 14th inst., at 1 p.m.:—

The accounts for the six months ended 31st December, 1887, show a net result which enables the Directors to add the usual proportion of the receipts to the reserve fund, to recommend a dividend at the rate of 15½ per cent. per annum, and to carry over a balance of £209. 4s. 8½d. to the next account. The same dividend was paid in the corresponding period of 1886. In the six months of 1887 there were 27 pay-days instead of the usual number of 26, and therefore the item of salaries includes 27 payments, while the receipts, on the other hand, only include the takings of 26 weeks. This fact accounts for half the increase in the item of salaries as compared with 1886. The other half of the increase is due to the annual increment to the clerks' salaries. The drawback received from the insurance company at the expiration of the yearly policy in August, 1887, for the days the repairing ship was in port was £388. 16s., which is in excess of the usual half-yearly charge for insurance of steamer by £63. 6s. Consequently the item for insurance does not appear in the annexed accounts. The excess of £63. 6s. will be carried to the credit of the insurance account for the half year ending June, 1888.

All the Company's cables are at the present time in good working order, but the Norderney cable, belonging to the Government, is interrupted, and the engineer is engaged in repairing it. The number of messages transmitted in the six months was 1,695,360, against 1,691,280 in 1886, but the length of the messages was only 11·03 words against 11·11 words.

The Board has long been endeavouring to obtain a renewal of the French Concession, and on three occasions within the last two years they have had strong grounds for believing that those efforts would be crowned with success. Unfortunately, the English Government have changed their policy, and propose to take into their own hands at the expiration of the Company's French and Belgian Concessions in January, 1889, the working of telegraphic communication with Holland, Germany, Belgium and France. This change of policy was communicated to the Board in a letter addressed to the Chairman of the Company by the Chancellor of the Exchequer early in November, and the arrangements about to be concluded in Paris were thus frustrated. The Postmaster-General has since that time informed the Directors that Her Majesty's Government have decided not to grant any extension of the Company's license for landing cables on the shores of this country, or to sanction a continuance of the working arrangement between the Company and the Post Office, as defined by the agreement of 11th July, 1868, beyond the date fixed by that agreement. The Belgian Minister of Posts and Telegraphs has also informed the Directors that it has been decided not to renew the concession granted to the Company for landing cables on the Belgian shore. In these circumstances negotiations are being carried on between Her Majesty's Government and the Board, and when these negotiations are terminated, the result will be made known to the shareholders without delay.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 27th January amounted to £3,142, and for the week ended February 3rd to £2,730.

THE CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of January was 4,064, estimated to produce £3,300, against 3,957 messages, producing £3,218, in the corresponding month of last year. The traffic receipts for the month of October, estimated at £2,900, realised £3,024.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this company for January amounted to £1,943, and for the corresponding period in 1887 to £1,904.

EASTERN TELEGRAPH COMPANY.— The traffic receipts of this company for the month of January, 1888, amounted to £56,164, and to £53,435 in the corresponding period of 1887.

EASTERN EXTENSION TELEGRAPH COMPANY.—The traffic receipts of this company for January, 1888, amounted to £39,878, and for the corresponding period in 1887 to £39,331.

THE GREAT NORTHERN TELEGRAPH COMPANY.—The latest traffic receipts of this company are as follows:—Receipts in January, 1888, £21,400, against £20,400 in the corresponding month of 1887, and £19,880 in 1886.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.— The traffic receipts of this company for the week ended January 27th, 1888, after

Digitized by Google

deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £1,764; and for the week ended February 3rd £1,562.

THE WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this company for the month ended 31st January, 1888, amount to £4,800.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated receipts of this company amounted to £3,209 for half month to 31st January, as compared with £2,831 last year. The October receipts, estimated at £5,371, realised £5,545.

PERSONAL.—We learn that Mr. A. C. Cockburn, who has been connected with the City and Guilds Technical College, Finsbury, since its foundation as Demonstrator in the Electrical Department, has resigned his appointment, having been appointed Manager to the Acme Electric Works, at 45, Tabernacle-street, Finsbury.

THE ELECTRIC APPARATUS COMPANY, Limited.

Head Office and Warehouse: 50, Bow Lane, Cheapside, E.C.
Depots: 4, Charing Cross, S.W., and 65, Faulkner St., Manchester.
Works: Arnold Road, Bow, E.

Electric Light Fittings, Edison-Swan Lamps, Schuckert's Ammeters, Voltmeters and Speedometers.

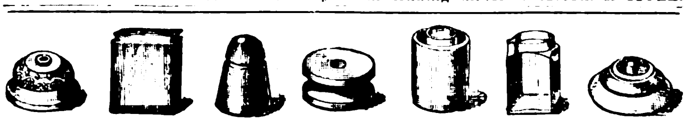
Specially Low Quotations for Electric Light Cables

BELLS, INDICATORS, BATTERIES, WIRES, &c.

MEDICAL APPLIANCES.

SHIPPERS AND THE TRADE SPECIALLY STUDIED.

NO CONNECTION whatever with any Firm trading under a SIMILAR TITLE.



J. STIFF & SONS, LAMBETH, LONDON,

MANUFACTURERS OF

VITRIFIED SWITCH BLOCKS,

Tubes for Electric Wires, Plain and Coloured Roses and Pushers,

GLASS LECLANCHE JARS, POROUS AND STONEWARE CELLS, INSULATORS, CHEMICAL APPARATUS AND CRUCIBLES.

CARBONS.

THE BARNSLEY CARBON CO.,

Manufacturers of

PURE CARBON POINTS, TUBES, FILTERS, CELLS, AND BATTERY PLATES

Of every description.

WORKS: BARNSLEY.

London Agency and Stores: THE GLOBE ELECTRICAL & ENGINEERING CO., 7, Carteret-street, Broadway, Westminster.

TELEGRAPHIC ADDRESS: "CARBON, BARNSLEY."

FREDK. LACK and SON,

90, STRAND,

CONTRACTORS FOR SHIPS' LINEN & BEDDING.

ALSO FOR

Household and Cabin Furniture, Carpets, Linoleum, China, Cutlery, and Plate for Export.

TELEGRAPH STATIONS FURNISHED THROUGHOUT.

Contractors to the Telegraph Construction and Maintenance Company, Eastern, Eastern Extension, Brazilian, and African Direct Telegraph Companies.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 509.—Vol. XX. FRIDAY, FEBRUARY 17, 1888. Price 4d.

NOTES.

We print elsewhere the full text of a Report of the Lighting Committee of the parish of St. James's, Westminster, on the Provisional Order sought to be obtained by the South Metropolitan Electric Lighting Company. It will be seen that the report is moderate and sensible in its tone throughout. We therefore think that the text will be of interest and advantage to those of our readers who may be engaged on schemes for central-station lighting in assisting to form an opinion as to the view which might fairly be taken by the local authority. Most of the objections raised upon points of detail are such as we should ourselves either be inclined to agree with, or else to suggest a *via media*, probably acceptable to both parties. The principal point upon which the Vestry would, we think, be wrong to insist is that wherein they propose the omission of the clause restricting the compulsory supply to premises within twenty-five yards from any main already laid. The Vestry has the wisdom to recognise in its preamble that "any undue restriction would probably interfere with the working of the Order on commercial principles, and therefore indirectly affect prejudicially the interests of the consumers." Now, this clause, which allows the company a choice in the direction of their operations, is absolutely essential to the success of the undertaking during its earlier stages. There is one objection raised, however, upon which we have little doubt that the Order will be quashed—unless serious alterations are made. The Vestry rightly observes that a capital of £250,000 is utterly inadequate to a scheme of the magnitude proposed.

The speech of the Hon. H. R. Brand, who presided at the Submarine Telegraph Company's meeting on Tuesday, has removed all doubt as to the steps which have been taken by the British Government to get possession of the company's cables. The French Government had virtually promised a renewal of the concession, when the English Foreign Office intervened and succeeded in preventing that renewal. We are still left in doubt as to the terms which the company is offered in compensation for this summary extinction of its rights—rights which are recognised at all events on the French side of the Channel, and which were as fully admitted by the English Government itself only ten years ago. But whatever the terms may be we are convinced that they will bear but a remote resemblance to those foreshadowed in the inspired paragraphs which went the round of the press a few months ago. The Central News announcement on the subject yesterday, which we print elsewhere, is probably nearer the truth, although for the most part based on mere conjecture.

It is worth while to remember at this moment that the exceptionally high dividends which this, the oldest, cable company has been able to pay until now have not been extorted by excessive rates. As a matter of fact, the tariff over all the cables owned by the Submarine Telegraph Company has for many years been fixed by the Governments represented at the International Telegraph Conference, not by the company, although with its concurrence.

The paper read last week before the Society of Telegraph-Engineers and Electricians by Mr. Kenneth D. Mackenzie on the Distribution of Electricity by means of Transformers contained some useful information, but it must be allowed that a good deal of the science is, to say the least, calculated to upset one's preconceived ideas, and will probably meet with some severe criticism. Mr. Mackenzie is a loyal adherent of the Gaulard-Gibbs theory of inductional phenomena, and he therefore accepts views which differ widely from those of such men as Mr. Kapp, Mr. Ferranti, Dr. Fleming, Dr. J. Hopkinson, *et hoc genus omne.* Mr. Mackenzie was himself careful to point this out. "It was only," he tells us, "when M. Gaulard came to the conclusion that induction apparatus constructed upon the theory founded by Faraday and exemplified by Ruhmkorff was unsuited for the purpose, that a step was made in the right direction." We learn this fact with considerable regret and even with some apprehension, because the authors whom we have named above have hitherto been content to follow up "the theory founded by Faraday," and it seems unfortunate that men whom we have been led to regard as amongst the leading exponents of the progress of the science should have been so miserably misled. We could wish that M. Gaulard had put this matter right before we had ourselves learnt from them so much that we shall now, it appears, have to unlearn. It is, nevertheless, some consolation to reflect that the blame must primarily rest with Faraday and Clerk-Maxwell, with whom it is perhaps excusable to err.

Accepting the Mackenzie-Gaulard dicta, we find that many curious consequences ensue. As these points of divergence from the theory hitherto recognised will doubtless

Digitized by Google

have received discussion at the meeting of the Society on Thursday evening (which at the time of writing has not yet taken place), we shall be content for the time to refer briefly to the four points "which are now known" (by the MACKENZIE-GAULARD school) "as essential features of transformer construction," and which "may, undoubtedly, be ascribed to M. GAULARD" (a claim, by-the-bye, which we think no one will be inclined to dispute). These points are as follows:—1. The reduction to a minimum resistance of the primary and secondary circuits. 2. The obtaining of a maximum coefficient of induction in the two circuits with a minimum in the dimensions and weight of the apparatus. 3. The placing of the primary and secondary circuits in identical positions in respect to the core or magnetic field. 4. The proportioning of the two circuits, primary and secondary, so that their metallic mass should be equal.

THREE at least of these conditions serve very well to accentuate the difference between the ideas expounded by Mr. GISBERT KAPP and Mr. KENNETH D. MACKENZIE. Mr. KAPP attaches primary importance to questions relating to the magnetic cycle of the iron core; Mr. MACKENZIE, ignoring the core, fixes his attention upon the coils, and attaches the highest import to a point which Mr. KAPP in his turn ignores—namely, the direct mutual induction of the two circuits independently of the iron. If we thought it safe to take sides wholly and unreservedly with Mr. KAPP we should remark, on the four "essential conditions" of M. GAULARD, that the first is not true for a transformer working in parallel; that M. GAULARD has not succeeded in the second; and that the third and fourth are conditions which in themselves neither add anything to nor detract from the efficiency of the apparatus. We will only remark further at present that since Mr. MACKENZIE'S method of treatment involves the consideration of *current* generated in the secondary, rather than E.M.F., it is on that account peculiarly difficult to grapple with, especially for those accustomed to the more usual methods. Perhaps this explains the singular fact that in Mr. MACKENZIE'S hands the secondary current varies as the *square* of the primary current.

IT is pleasant to turn from these abstruse considerations, where even doctors differ—or at least Mr. MACKENZIE differs from the Doctors—and to recognise the great value of the information conveyed by the author on several points of practice, especially those connected with the running of circuits for alternating currents; and also the lucid and interesting manner in which the paper as a whole is written. The description of the Kingdon dynamo is peculiarly interesting, and we venture to think that this machine has a future before it..

WE were favoured some months ago with a private view of the "appliances" of the Armstrong Electric Light and Power Company; but as our inspection, like the company, was strictly limited, we took no notice of it in these pages. How very wise the company was in restricting its exhibits to a carefully-locked cabinet containing "the batteries," and the outsides of seven sealed packets, the contents of which, marked with the days of the week consecutively, had to be administered to the said batteries, is proved by what has since happened. The Armstrong Company has issued its prospectus, and its demand for the modest sum of £20,000 by way of capital has actually met with some response. One of the subscribers now writes to a contemporary under grave suspicions that he has lost all he subscribed; and certainly, if the description in the *Financial News* of the manufacturing premises occupied by the company is at all accurate, it certainly does seem probable that the subscribers will gain nothing but a little valuable experience. Our own experience cost us only a short walk; and we strongly advise capitalists to always invest in that cheap and healthful exercise before risking their money on inventions which are shrouded in mystery, and about which technical journals are not allowed to form an opinion.

THE discussion at the Physical Society on Saturday last on the use of the term "magnetic resistance" to indicate the ratio between magneto-motive-force and magnetic flux (or in still more familiar terms, between ampere-turns and lines of force per unit area), may be taken to stamp with authority the employment of the term in question. We regard this result as satisfactory, because, while we have not, for our own part, been able to see any valid objections to its use, yet so long as Dr. HOPKINSON and Mr. OLIVER HEAVISIDE'S objections remained unanswered, we have naturally felt a little uncomfortable when applying it. If these gentlemen still hold to their repudiation of the term, perhaps they will now suggest an equivalent.

WE are glad to see that the first annual meeting of the Taunton Electric Light Company has passed off so satisfactorily. Some of the shareholders of the local gas company have of late busied themselves in spreading rumours disadvantageous to the financial position of the company. The payment of a 5 per cent. dividend, carrying forward a substantial balance satisfactorily disposes of these rumours. The practical working of the installation evidently meets with the full approval of the major portion of the inhabitants, who are quite prepared to continue paying the extra cost entailed by the use of electricity.

THE opening of the New Electric Club House in New York seems to have been quite a brilliant affair, and promises well for the future of the electrical profession. The building is described as spacious and handsome, and so arranged as to meet the requirements of a Scientific Society while fulfilling all the purposes of a professional club. About 400 members engaged in electrical business or research have been already enrolled; and it is probable that similar clubs will be started in other large towns of the United States. We know of no institution in this country exactly corresponding with the New York Electric Club House; nor perhaps is there any need for it, the habit of Englishmen being emphatically to drop their business when they go to their club. England, however, possesses an abundance of separate institutions representing all branches of science and industry; and it is mainly to make up for its

Digitized by Google

deficiency in this respect that in New York the functions of club and institute are sometimes combined.

PROF. ROWLAND dwelt on this point in the course of his interesting address at the opening of the Electric Club, remarking upon the advantages which FARADAY enjoyed in being so closely associated with the science of Europe, encouraged by the Royal Society at which to announce his discoveries, and by the Royal Institution in which to make them—advantages which no man, however naturally endowed, could have obtained in America either then or now. Prof. ROWLAND'S address, brilliant and sympathetic as a scientific memoir of FARADAY, was still more valuable as an appeal to American public spirit to emulate the example of the old country, which has always been in the forefront of scientific progress.

OUR New York correspondent calls attention to the utilisation of wind-power for electric lighting. This idea is, of course, a very old one—we believe it was first propounded by Sir WILLIAM THOMSON in his address to Section A of the British Association in 1881, though Sir WILLIAM was careful to point out that the successful application of this force would necessarily be confined to a small scale of working. But, as our correspondent rightly says, it is only since storage batteries have obtained their recent development that the scheme has come within the range of practice. We have reason to believe, however, that a plant of this description will be on view at the forthcoming Glasgow Exhibition, and we hope shortly to be able to give some further account of the arrangements adopted. Meanwhile we may refer those of our readers who are interested in the subject, to an article in our issue of August 27th, 1886, in which some numerical data will be found.

St. Pancras Station.—We understand that the Midland Railway Company are about to light the St. Pancras Station with the Thomson-Houston system.

Cheltenham.—At the meeting of the Cheltenham Town Council on Monday last a resolution was unanimously adopted directing the Streets and Highways Committee to report upon a scheme for the introduction of electric light, and giving power to obtain the advice of an expert.

Private House Lighting.—The electric light is being introduced into the country residence of Baron Schroeder at Egham. The plant will consist of two gas engines and two of Elwell-Parker's latest inverted B type dynamos. The work is in the hands of Messrs. Drake and Gorham.

Lighting of the Royalty Theatre, Glasgow.—This theatre has recently been supplied with an electric lighting plant by Mr. Geipel, of Edinburgh. The installation was brought into use for the first time on Monday evening last. We shall shortly give a further detailed description of the plant.

Paris.—A circular issued by MM. Ch. Mildé, Sons and Co., of Paris, informs their clients that, owing to the exigencies of the regulations made by the Municipal Council affecting electric lighting, they have been compelled to abandon the idea of establishing a central lighting station in the quarters of Monceau, Malesherbes, Ternes, and Champs Elysées.

The American Bell Telephone Company in Mexico.—The First District Court of Mexico has pronounced a decision confirming the validity of the Bell Telephone patents in that country. The action had been brought in order to test the right of importing telephones of German manufacture. There will, however, be an appeal to the Supreme Court.

Edmondson's Calculating Machine.—We are informed that Mr. Edison has recently ordered one of these remarkably ingenious machines for his new laboratory at Orange, New Jersey. This apparatus is capable of performing addition, subtraction, multiplication and division, there being no limit to the number of figures with which it is capable of dealing.

Spanish Tender for Telephone Service.—The *Madrid Gazette* of Monday last (February 13th), contains a Royal Order authorising an invitation for tenders for the establishment and working of a telephone service in Cordoba, subject to the conditions published in the official journal of 15th June, 1886. Tenders are to be adjudicated upon on March 16th next.

The Electric Light in Railway Carriages.—At the meeting on Wednesday of the Great Northern Railway Company the Chairman (Lord Colville of Culross, K.T.) stated that they had been engaged on experiments connected with the use of the electric light in their carriages, for which purpose the proprietors' sanction was required for an expenditure of £552. They had at present three trains running lighted by electricity.

A Large Galvanometer.—A large galvanometer has just been completed by Mr. Forée Bain for the United States Government. It is a combined tangent, sine, cosecant, and differential galvanometer. It will measure currents up to 1,000 amperes, E.M.F.'s up to 3,000 volts, and resistance up to 10,000,000 ohms. This instrument has been on exhibition at Giles Bros. and Co.'s, New York, where it has attracted much attention.

Telegraphing Bismarck's Speech.—On the day of Prince Bismarck's recent speech in the German Reichstag, which contained 10,997 words, no fewer than 1,218 press telegrams, comprising 194,296 words, were sent from Berlin to 326 different places in Germany and abroad. The forwarding of these telegrams was effected by 235 officials on 222 instruments, sixty of these being Hughes, 155 Morse, and 7 Etienne. The longest telegram sent to any non-German journal was that addressed to *The Times*.

New Zealand.—According to advices from Auckland an experimental installation of arc lights to illuminate Queen-street was in preparation for Christmas, the undertaker being Mr. Firth, who has offered the use of the lights gratuitously for a fortnight, previous to entering into an engagement with the Corporation. Messrs. Ashcroft, who had previously contracted to supply the light but failed in some of the conditions, owing, as is alleged, to the interference of the telegraph department, are claiming damages from the Corporation.

Railway Tunnel Lighting in Russia.—According to the *Engineer*, upon the line between Kieff and Odessa some of the railway tunnels are provided with a plant for lighting the trains which traverse them by a method similar to that carried out upon the underground railway in Glasgow. There are three circuits—in different tunnels—of 2,000ft., 1,460ft., and 6,540ft. respectively. The rails are used for the return conductor, and the main cables are laid in a central channel between the tracks. Contact is made in each tunnel with the wire for that circuit by trailing pulleys on the car axles. Each car has its own contact with the wire, so that all complicated connections of coupling a train are avoided. The company has applied the system to seventy-four cars, and they report that the expense of the system is less than one-third the cost of gas.

Digitized by Google

A Syndicate of Electricians in Belgium.—According to the Brussels correspondent of *Industries*, it is proposed to establish an electrical syndicate; but there will be some difficulty in arriving at a proper understanding as to the share each firm is to have of the business that comes in. One of the main subjects for which the syndicate is being formed is to light the town by electricity, and in order to do this it is proposed to buy up the gasworks. Failing this, which would cost some millions of francs, a central station would be established to supply the electric part of the town. The syndicate also intends to acquire the most important electrical patents, so as to put down outside competition. The project is very good on paper; but whether it can be realised, says our contemporary, is another matter.

The Thomson-Houston System in the West of England.—The *Somerset County Gazette* says:—Owing to the damaging statements made by Alderman Bruford and other shareholders in the Taunton Gas Company respecting the reliability of the electric light in that town, members of the Local Board and other gentlemen who are desirous of seeing the electric light introduced into Weston have privately visited Taunton upon several occasions during the past few weeks, to test the accuracy of Mr. Bruford's statements, with the result that they are unanimously of opinion that there is no justification for such statements, the light upon each occasion being in every respect equal to what it was when the deputation visited Taunton on November 18th, 1887. It has now been definitely decided to use only the system adopted in Taunton (the Thomson-Houston) in the event of the electric light being introduced into Weston-super-Mare

The Paris Exhibition, 1889.—As announced in our last issue, a preliminary meeting of intending exhibitors at the Paris Universal Exhibition, 1889, was held on Monday last at the offices of the Society of Telegraph-Engineers and Electricians, which was attended by several of the leading London electrical firms, and it was "Resolved that in the opinion of this meeting it is desirable that the Society of Telegraph-Engineers and Electricians should accede to the request of the Director-General of the Exhibition that they should undertake the organisation and general representation of the British electrical section." We understand that a circular will probably be shortly issued calling a more extended meeting, with the view of ascertaining the full extent to which British electrical industry will be represented at the Exhibition. Already many important firms besides those represented at the meeting on Monday have signified to the society their intention of exhibiting.

Weston-super-Mare.—A correspondent writes:—"At a meeting of the Town Commissioners held on Wednesday, the 8th inst., an amendment to the minutes of the Lighting Committee, which recommended the adoption of twenty arc lamps on the sea front, was carried after a lengthy discussion, the amendment being to the effect that the minutes of the Lighting Committee be not accepted. At the same meeting of the Board a proposal, which was carried unanimously, was made that a committee of the whole Board should reconsider the subject, with a view to the town undertaking the lighting and providing its own appliances therefor. This is as it should be, for the electric light is regarded with considerable favour in the town, which has been shown by the several deputations which have waited upon the Board, and also by the large number of letters on the subject in the local papers. It is a great pity that it will not be ready for the ensuing season, when the Somerset County Agricultural Show will be held here."

Underground Wires at Brooklyn.—The Brooklyn Electrical Subways Board of Commissioners do not seem to have prospered in their further endeavours during the past year to get the aerial wires of that city put underground. According to their fourth annual report, just issued, the operations of the Board have been virtually stopped by another Brooklyn Board, the Board of Aldermen, who refused to let the streets be opened for the construction of the subways until compelled to do so by the Courts. Matters are going more smoothly now, and there is a growing desire on the part of the several electrical companies to comply with the law. Most of the wires have been removed from the poles; but unfortunately the poles still remain standing, with a few wires hanging on to them belonging to the police department, who profess their inability to remove them. This want of co-operation between the several city authorities or Boards has led to the suggestion that the elevated railroad system should be utilised for all kinds of wires, thus dispensing with the conduit system as well as with poles.

The Exhibition of Apparatus Connected with Atmospheric Electricity.—The Royal Meteorological Society has issued the following circular:—"The Council of the Royal Meteorological Society have arranged to hold at 25, Great George-street, Westminster (by permission of the Council of the Institution of Civil Engineers), on March 20th to 23rd next, an Exhibition of Apparatus connected with Atmospheric Electricity, including Lightning Conductors, Photographs of Lightning, and damaged objects. I am therefore instructed by the Exhibition Committee to invite your co-operation, as they are anxious to obtain as large a collection as possible of such apparatus, &c. The committee will also be glad to show any new meteorological instruments or apparatus invented or first constructed since last March, as well as photographs and drawings possessing metereological interest. Should you be willing to co-operate in the proposed exhibition, I should be obliged by your furnishing me (not later than March 1st) with a list of the articles you will be able to contribute, and an estimate of the space they will require.—I am, sir, your obedient servant, William Marriott, assistant secretary."

The Lighting of Victoria Station.—The Victoria Station of the London, Brighton, and South Coast Railway Company has at length been supplied with electric lighting plant. There are thirty-five arc lamps of 2,000 nominal candle-power, supplied by current from a single dynamo of the Woods type. The lamps are arranged in series, all on one circuit, but this circuit is divided into four sections, the ends of which are led to a switch-board in the dynamo room. The dynamo automatically adjusts the position of its brushes in accordance with the number of lamps burning. To this end the spindle bears at its termination a small frictional wheel which can be put in gear with either of two other frictional wheels on a swing frame. This frame is connected to the cores of a pair of solenoids traversed by the current, and if the current becomes greater or less than the normal, the cores move the swing frame to bring the frictional wheels into gear, and through their agency and that of a train of toothed wheels, to move to brushes round the commutator. The power is derived from a 16 horse-power (nominal) Crossley gas engine. The installation has been carried out by Messrs. Verity and Sons, of King-street, Covent Garden.

The Institute of Medical Electricity.—We have received a copy of the prospectus of the Institute of Medical Electricity (Limited), which is advertised in our columns this week, and note that the company seems thoroughly genuine and *bonâ*

Digitized by Google

fide. A very encouraging feature is that several of the best medical and electrical men have combined to support the institute. Accompanying the prospectus there is a memorandum of recommendation, signed by eight doctors of eminence, including a past president of the Royal of Surgeons and a vice-president of the Royal College of Physicians. There is also a list of "visitors," containing the names of an equal number of medical and electrical men of the highest reputation and position, among the latter being several past and present officers of the Society of Telegraph-Engineers. The fact that Mr. W. Lant Carpenter, B.A.,B.Sc., M.S.T.E., is one of the directors, and that two others, including the manager, are associate members S.T.E., will be a guarantee that the much abused subject of medical electricity will be dealt with in a proper manner, and that the high standard they have adopted for the institute will be maintained. The directors do well to offer the shares to medical and electrical men in the first instance, for we cannot doubt that for so excellent an undertaking the small capital asked for will be readily subscribed by them, and it is only right that the control should be in the united hands of those professions. Those of our readers who require fuller information cannot do better than write to Mr. H. Newman Lawrence, the manging director, at the temporary office of the company, 16, Clifford's-inn, E.C.

Electric Lighting of the City.—The Streets Committee of the City Commission of Sewers, to whom it was recently referred to further consider the proposed arrangement with the Anglo-American Brush Electric Light Corporation for lighting a district of the City by means of electricity, have submitted their report to the Commission. The company have agreed to deposit £1,000, to be forfeited in the event of their not commencing their work within six months from the signing of the contract or not completing the installation by October, 1889, and also to the insertion of a clause that in the event of the Commission seeing reason to terminate the contract for public lighting within the seven years the company's exclusive right of way for private lighting shall then cease. The district proposed to be lighted commences from the front of the Royal Exchange, and comprises as much of the City as lies between the Poultry, Cheapside, St. Paul's, Ludgate-hill, and Fleet-street on the north, and Queen Victoria-street and the Embankment on the south. The contract for public lighting is to be for seven years, from the 31st of October, 1889. The price for each arc lamp of 2,000-candle power is to be £26 per annum. The Commission propose to grant to the company, so far as they are able and conditionally on the company commencing and completing the public lighting, the exclusive right of supplying private lighting during the same period. The license given for private lighting is to be subject to immediate termination if it is decided by any court of law that the Commission cannot legally grant such powers, and in that event the company are to be at liberty to determine the contract as to public lighting by giving a month's notice. The report will come before the Commission for discussion on Tuesday next.

Incandescent Lamps in Mines.—A writer in the *South Wales Daily News* says:—"It seems to be now pretty well understood that the universal adoption of the electric light system in our collieries is only a question of time. Several mining districts, Treharris, Cwmpennar, and Maerdy, for instance, the coruscations of whose beacon-like electric luminaries are to be seen at a distance in the night, have enjoyed for some time past the advantages afforded by the new light on the surface. The only difficulty and misgiving I hear of that are likely to militate against the idea of flooding the inner regions of our collieries with electric light are the high price of the electric lamp, and a fear prevailing among colliers that the general utilisation of it may lead to a dangerous neglect of duty in the ventilation of the works. The slow poisoning process of the inhalation of air impregnated with gases would evidently do more havoc with the lives of underground workmen than an occasional explosion. But a revival of trade would soon enable all to surmount the monetary difficulty, and the power to inspect mines with which the miners themselves are now invested would, one should think, be a sufficient safeguard to prevent the neglect apprehended. Advantage was taken of this provision of the new Act last week, at Mountain Ash, where, without giving any previous information to either the management or the workmen, six experienced colliers, summoned by the checkweigher for the purpose, explored the colliery in which they were employed, and afterwards presented a satisfactory report. I expect that presently the underground population of our colliery districts will hail with great delight the dawning of the new era of the electric light turning their night into day."

Lighting of North Shields Markets.—The electric lighting of the North Shields markets, which has been carried out by the Gülcher Electric Light and Power Company, has now been in working order for over a month. The installation has been carried out in a very complete manner, and we understand that it is giving entire satisfaction to the Corporation. The plant consists of a 20 horse-power nominal Marshall's compound undertype engine, fitted with a long crank-shaft extended on one side of the engine, and supported by a third bearing; the extended length of shaft provides sufficient room for the addition of one or two extra pulleys or fly-wheels, an extension of the installation being contemplated. By this method extra dynamos may be driven without counter-shafting. The engine is very complete in every respect, being fitted with a Worthington pump for feeding the boiler, steam trap for draining the jackets, and relief valve to the low-pressure cylinder. The engine drives by an endless band on to a 12-unit Gülcher compound-wound dynamo, giving a current of 185 amperes at 65 volts, at a speed of 1,000 revolutions per minute. The machine is mounted on a cast-iron sliding bed plate, with tightening screws, and works without any sign of sparking. The current from the dynamo is taken to a handsome main switch and cut-out board, mounted on a slate slab, carrying 14 sub-circuit switches, with cut-out to each. Above the switch-board a rheostat frame is placed, carrying 16 resistance coils, with adjustable sliding contacts. By this arrangement all resistance coils are kept in the engine room, and under the eye of the driver. A voltmeter and ammeter are provided for measuring the current and E.M.F. After the current leaves the switch-board it passes by single circuits of $\frac{7}{18}$ cable to the 15 2,000 candle-power arc lamps arranged in two lines along the markets, and is carried back by the main negative lead to the switch-board. All the cables are run in continuous casing, grooved out to carry the arc light circuits, and also an incandescent circuit for lamps on each side of the market. The arc lamps are of the usual Gülcher globe type, with telescopes for lowering the globes for recarboning, each lamp being fitted with a raising and lowering gear. The stalls in the markets are lighted by incandescent lamps, suspended by flexible pendants from the ceiling; the engine room and other offices are also lighted by the same means. This installation affords an example of the convenience of the parallel system of arc lighting for places where the lamps are placed within a reasonable distance of the dynamo, and a combination of arc and incandescent lamps is required.

A PROPOSED NEW PUBLIC TELEPHONE SYSTEM FOR CITIES AND LARGE TOWNS.

BY WALKER MOSELEY.

(Continued from page 314.)

In returning to the consideration of the first great difficulty in the way of a distributive telephonic system, viz., to secure insulation, I know it is important to clear away many conflicting opinions and doubts which beset telephonic experts, as such. Any attempt to be at the same time concise and precise in carrying that out would delay the realisation of a general unanimity amongst that elect class of telephonic technical experts which in any sense guides telephonic financial experts. I trust, therefore, the following remarks will be carefully weighed, for at the present time it begins to be seen that if confusion of ideas should exist much longer concerning the most troublesome facts in practical telephony, inferences will be drawn that may seriously shake public confidence in public telephony. The confusion I am more especially referring to is that which may be characterised as a half public confession that, however perfectly the system may be insulated, there will remain a liability (to use an Americanism) to "cross talk," or I would rather say *stray talk.* Now, this is true only on the supposition that an "earth" return must be always used. So long as that is in vogue the following must ensue as a rather common coincidence, viz., that when speaking through a line whose route outspans a shorter line—no matter how perfectly both lines may be insulated—the speech through the long line could be heard by listening at the telephone at either end of the short line. All that can be said to minimise this fault is that the speech on the short line will be "faint." But "faintness" is comparative in more senses than one. In some cases of faintness there is plenty of volume if the articulation were good. In other cases the articulation is so good that although only one-hundredth part of the volume of the speech—to one used to the telephone—is perfectly intelligible without effort on the part of the listener. Indeed, I have frequently heard a score voices at once, several of which voices were so characteristic that I have followed every word of whichever voice I chose to follow. Whereas, if the voices were listened to in their ordinary volume in a room, the combined volume of sound would prevent any voice being intelligible. An agreement as to these facts would cause great hesitation in resorting to any great outlay with the object of securing perfect insulation. But if a complete metallic circuit, or, in common phraseology, if a well insulated wire be used for the whole distance there and back, it is impossible for such effects to occur, and it at once becomes worth while to calculate whether it would not be worth while to incur even a greater outlay than ever dreamt of hitherto. Further consideration will also show that the very thing that is necessary to shut out *stray talk* is the only means that enables us to overcome our second great difficulty, viz.:—

2.—To Kill Induction.

Common conversation amongst telephone experts brings out more or less distinct but unanimous deprecation of the idea that a complete metallic circuit always kills induction. Mixed up with this flattering unction is a slight recollection of this elementary fact—viz., that the effects of induction are, in the absence of leakage, greater in proportion as the wires are better insulated. As a lecture table experiment a very simple demonstration is enough to reason from in the present instance. For example, take a coil of three wires, say a mile in length, wound simultaneously side by side. Connect up two of these wires as one telephone circuit, and the third wire as another. Speak on the double-wire circuit and listen on the other, when no sound will be heard; whereas, if two of the same wires are used as two separate circuits, then induction effects will be observed.

I am prepared to contend that there is no practical difficulty in securing similar results in general use without resort to more expensive means than present subscriptions will cover.

The system of distribution by which I propose to secure the above objects will be better understood after a careful examination of the illustrations and some further explanations in a later issue of this journal.

D and E (Fig. 2) represent two iron conduits shown in section in Fig. 3, K K'. I propose that a large proportion of the conduits shall be in section 2in. by 2½in., and the wires contained in metal tubes—to be explained more fully later on—to be of such a section that 100 will, with the addition

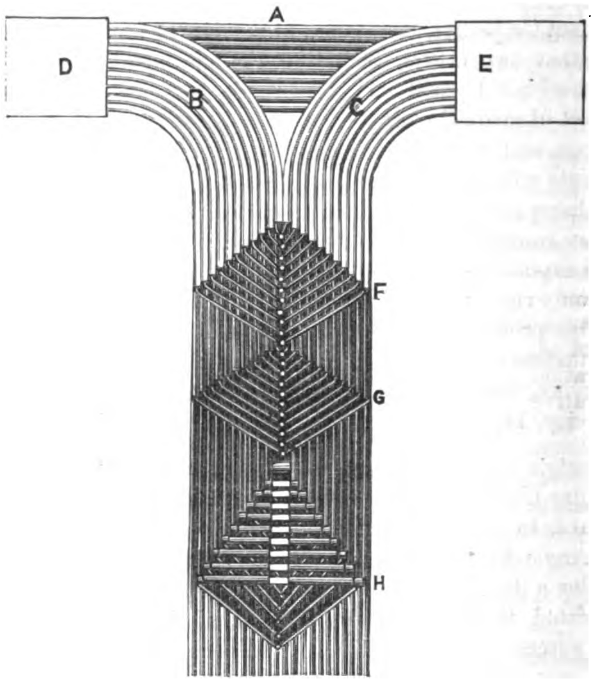

Fig. 2.

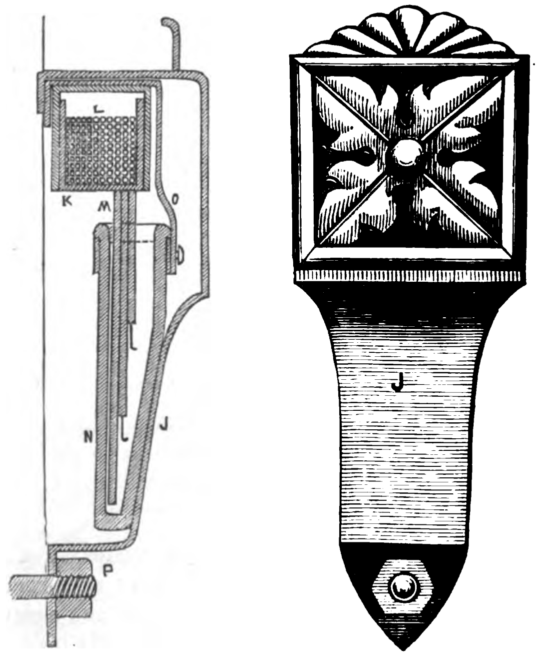
of a hemp serving on each tube, nearly fill the conduit K. A represents a series of these tubes running past a junction in the conduits, and B C turned down for jointing. But it must



Figs. 3 and 4.

be observed that where some are turned down for jointing, whilst others run straight on, they will usually be treated in a different order from that shown in the drawing, the object of the illustration being to show the method in its simplest form. F G and H (Fig. 2) are three series of ten-jointed, the lower

Digitized by Google

series showing the tubes bridged across with soldered joints. L (Fig. 3) represents 70 tubes in section, and M 30 tubes turned down, or, in other words, A, B, C, F, G, H (Fig. 2), shown in section and side view respectively. N is an earthenware well to be filled with oil, supported by the metal strap O. The letters J, J (Figs. 2 and 3), represent a metal cover to imitate an architectural truss, shown in front view in Fig. 4. The bolt and nut P secure the cover against the wall. Perhaps the most obvious of the advantages of this method of jointing the wires and insulating the bare joints is that every wire may be known by its relative position in the perpendicular series of joints, so that every conduit being numbered and every series of joints being numbered, the position of the wire will be given by a third number, thus $\begin{matrix}25\\13\\10\end{matrix}$, or 25—13—10, will mean conduit 25, junction 13, wire 10, so that not a moment will be lost in getting at any wire for testing or alteration, and in going over the process of laying the tubed wires in the conduits, waterproofing the same and making the soldered joints, it will be found that the time occupied will be less than the ordinary way of doing the same quantity of work. But, of course, to obtain this result, at the outset there is not only a set of mechanical contrivances for effecting each operation but for the jointing processes in new plant a set of operatives who have had years of training in similar work will be employed. The process devised for unsoldering any joint for testing or alteration is so manageable and expeditious that a joint can be undone and joined up again in half a minute, and no matter how many tests be made at any of the junctions, it will be seen that the whole series may be insulated in a moment by lifting up the oil-well for their immersion. The expedition attainable by this system for testing operations will enable one man to trace out a fault in a two-mile line in 36 longitudinal sections up to the particular section containing the fault within three hours. The number of operations involved, and the length of time necessarily occupied, will on this system be almost uniform for a line running through any given number of junctions. The supposition—based on precedents improved upon—is that faulty insulation in any longitudinal section of tubed wires will be exceedingly rare; but wherever it may occur a spare wire will be immediately joined up to bridge over the faulty length, and before all spare wires are used up additional wires will be laid alongside in a new conduit. It may appear strange to speak of a two-mile line being divided into thirty-six lengths, and it may be supposed that some practical difficulty necessitates laying up the wires in such comparatively short lengths. But that is far from being the case. One of the reasons for the adoption of short lengths is that as there will be no loss at the junction, neither of insulation nor conductivity, it would be bad policy to neglect any opportunity for providing for future contingencies of any kind so long as present efficiency is secured. Amongst other contingencies there is the uncertain proportion that will exist between long lines and short ones, as well as private wires. The latter having been up to the present a practically boycotted branch of telephony, calculations in detail under these heads will show that numerous junctions will tend to economy. But the greatest advantage will be that any imperfection in the form of either leakage or rupture can be immediately remedied, and every line can be kept practically in a uniform state of perfect insulation and conductivity.

In stating this I am not losing sight of the palpable disproportion between the amount of insulation obtainable between the wires and the tube, as compared with that between the tubes, and since the illustrations will show that each tube is intended to form the "return" for its own wire, it will appear that very little space is allowed for the insulation between the tubes. But I shall show later on how any failing of insulation between the tubes will be remediable without disturbing them in their respective conduits, whereas the wires can have a sufficient margin to protect them against all contingencies, with only a quarter of the material that the tubes would require. I shall presently proceed to describe the method of insulating tubing and laying up the wires, which, although well-known principles are introduced, will be found to fulfil several practical requirements by a new combination of parts and processes.

It will then be possible to form a fair estimate of the total cost of the scheme on the proposed scale. After submitting such an estimate, I will then describe where improvements may be made in all the instruments at present in use, with special references to long-distance telephony.

(To be continued.)

EXPERIMENTS ON THE CONDITIONS WHICH DETERMINE THE STABILITY OF A TELEGRAPH WIRE.

BY FRANK CAWS.

PART I.

It has heretofore been usually assumed amongst telegraph-engineers that the dip and stresses of telegraph wires may be calculated with sufficient accuracy for practical purposes by neglecting altogether the existence of a modulus of elasticity, and proceeding as if the wire were absolutely inelastic.

It is upon this assumption, for instance, that the table contained in Mr. Preece's paper "On Copper Wires" (read before the British Association, Manchester, 4th September, 1887) has been calculated.

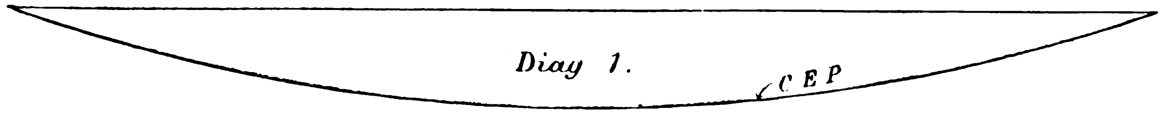
It is the object of the following paper to show that we cannot afford to neglect the elasticity of the wire.

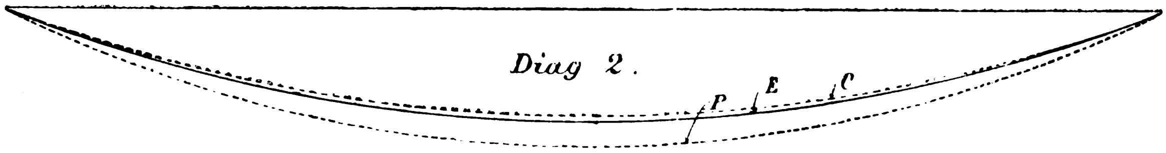
I stated, in a letter to *The Electrician*, 21st Oct., 1887 (without making special reference to the table issued by Mr. Preece, and as a general principle), that calculations of dip and stress due to various temperatures, if allowing only for expansion and neglecting elasticity, would give an incorrect result, greatly exaggerating the differences of stress and dip in winter and summer. I made this statement incidentally, in dealing with the question of springs on telegraph wires. Mr. Preece, in *The Electrician*, 28th Oct., 1887, wrote that I had "failed to realise the conditions which determine the stability of a telegraph wire." This remark compelled me to prepare a table of dips and stresses at various temperatures, which I published in *The Electrician*, 4th Nov., 1887. This table showed that when the expansion only was allowed for and the elasticity of the wire neglected, the results closely corresponded with Mr. Preece's table; but that when the elasticity was allowed for the differences from Mr. Preece's figures were considerable. My table of 4th Nov. was, as therein stated, founded upon a modulus of elasticity = 14,500,000lb. per inch of sectional area of copper wire. On the 9th Dec., 1887, I published in *The Electrician* further tables showing the stresses due to snow on the wires, and the capacity of springs to yield relief from such excess stresses. I mentioned that some text-books placed the modulus of elasticity for copper wire as high as 17,000,000lb., and added that, if such were the modulus, its effect would be to render the dips very slightly more, and the stresses very slightly less, than shown by my table of 4th Nov., founded on a lower modulus.

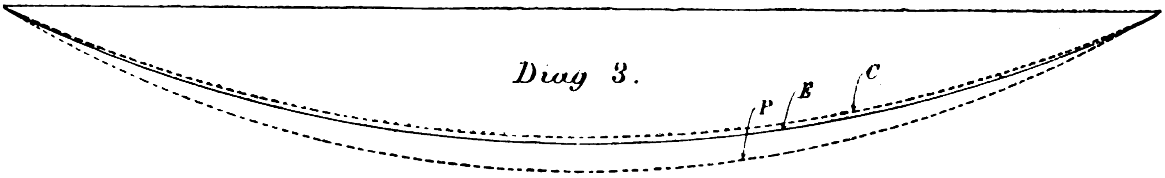
And at the same time I explained that the tables were all calculated as if the catenary were a parabola. On December 8th, 1887, I prepared a table of dips and stresses due to a modulus of 17,000,000lb., still calculative as if the catenary were a parabola. The dotted lines C on the diagrams 2, 3, 4, are given by my table of the 4th November. The firm lines E on the diagrams 2, 3, 4, are given by experiment, as hereinafter described. I cannot show on these diagrams 2, 3, 4 the line due to the 17,000,000lb. modulus, because at diagram 2 it lies between C and E, at diagram 3 it lies practically on E, and at diagram 4 it lies so small a distance below E as could only be shown by thickening the line E a little at its vertex. The lines P in these diagrams are given by Mr. Preece's table; and show almost exactly the effect of expansion on the wires *if* they were absolutely inelastic. The line in diagram 1 is marked C E P because it is the datum at which the tables and experiments are all made to agree in dip. Serious as are the differences between the dips given by Mr. Preece's table

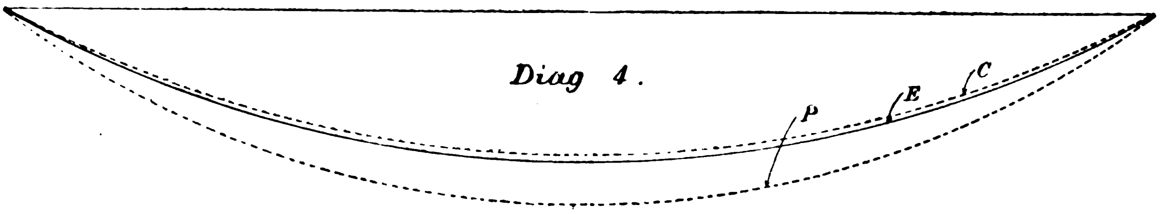
Digitized by Google

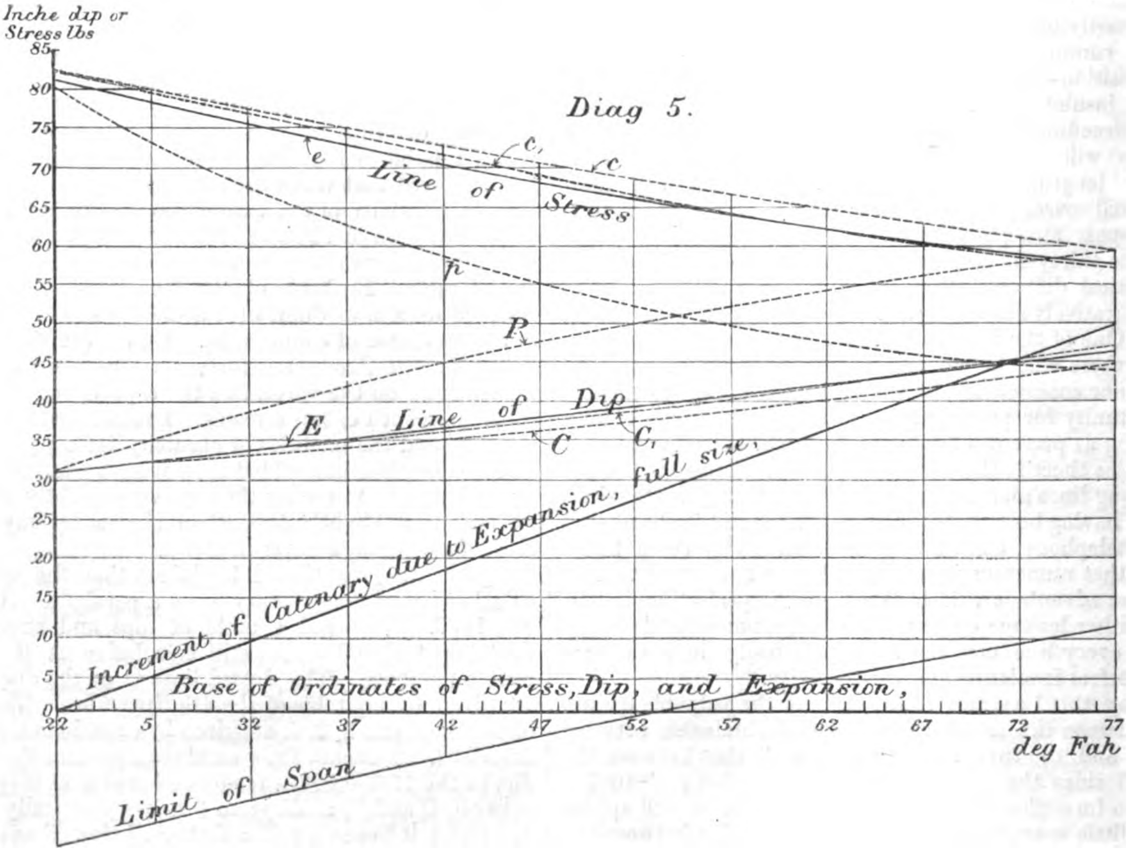
and by experiment, the differences of stress between Mr. Preece's table and experimental results are still more serious. This is shown by diagram 6, whereon the firm line *e* gives the stresses as per experiment, and the dotted line *p* gives the stresses as per Mr. Preece's table, while the dotted line *c* gives $\frac{1}{10}$in. per deg. F. By measuring the line *e* for any intermediate temperatures (between the points which were experimentally taken at 18deg. apart) the telegraph or telephone engineer will obtain the true stresses for such intermediate temperatures, agreeing with a factor of safety = 4 when









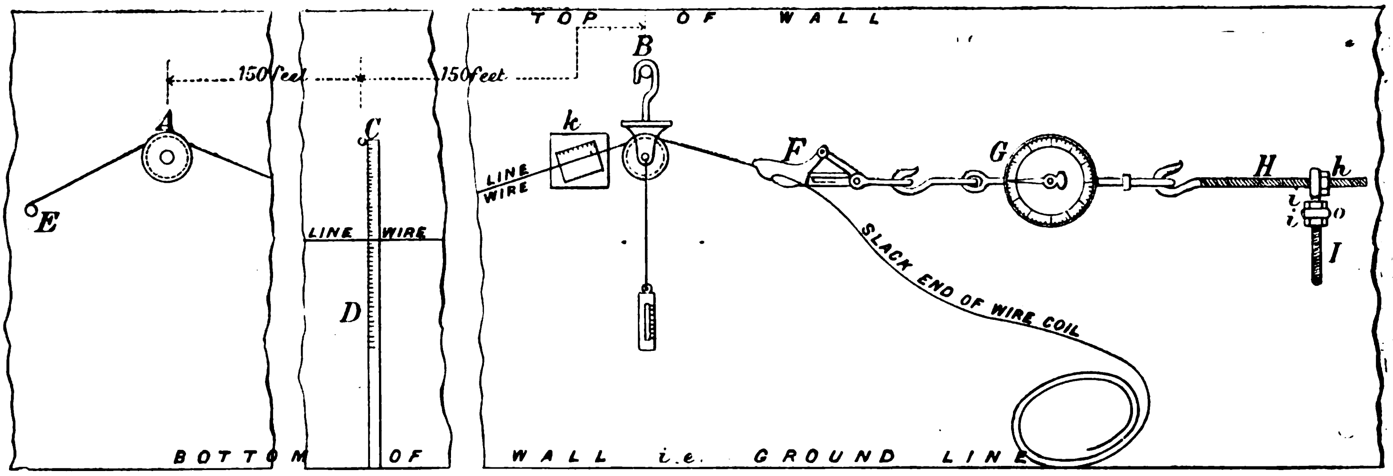


the stresses as per my table of 4th November, *i.e.*, for 14,500,000lb. modulus, and dotted line c_1 gives the stresses as per 17,000,000lb. modulus. The vertical ordinates of diagram 6 are to a scale of 25lb. stress per inch, or 25in. dip per inch; and the horizontal co-ordinates are to a scale of the breaking stress of the wire is 330lb. For example, at a temperature of 50deg. F. the stress will be found to measure, by scale on diagram 6, about 67lb., which will be correct. In order that this diagram 6 may be of still more value to telegraph and telephone engineers, I have repre-

Digitized by Google

sented thereon the experimental dips for various temperatures by the curve E, by means of which the dips for any intermediate temperatures may be found by scaling the diagram. For example, at 50deg. F., the dip scales 38$\frac{3}{4}$in., which is correct. It will be observed that the curvature of the line E is so slight as to be inappreciable, between 22 and 77degs. F. That is to say, the curvature is too small to show on the scale of the diagram. But the figures of the annexed table of experimental dips show the slight curvature which really exists; and a little reflection will convince the student that were there no curvature in the line E, diagram 6, the dips would become zero at about 123deg. F. below zero, which is absurd, because to have a zero dip we must have an infinite stress. Hence it follows that in diagram 6 the line E is a portion of a curved line, which, if continued, would evermore approach but never reach its base line, which base line is therefore its asymptote. The curve of dips marked P on diagram 6 is according to Mr. Preece's table. This curve bends the wrong way (viz., concave towards its asymptote), besides being, as I showed by diagrams 2, 3, 4, a long way wrong in its ordinates generally. The curve of dips marked C on diagram 6 is according to my 14,500,000lbs. modulus table, and the curved marked C_1 on diagram 6 is according to my 17,000,000lb. modulus table. Both C and C_1 bend the right way (viz., convex towards their asymptote), and while both are nearly the same as the experimental curve E, the line C_1 is so nearly identical with the experimental line E as to leave no room for doubting that 17,000,000lb. is the modulus of elasticity of copper telegraph wire, or is sufficiently near the true modulus for all practical purposes. Thus my immediate object in making these experiments—viz., the ascertaining of the true modulus, and testing my table—has been accomplished.

Diag 6.



With view to make diagram 6 of still more service to telegraph and telephone engineers, I have added a "Line of Catenary Increments." This line gives the full-size measure of increments to catenary arc (dating from 22deg. F.) due to expansion. For example, the expansion of the catenary arc, per 100 yards span, from 22deg. F. to 50deg. F., measures per the 50deg. ordinate on diagram 6, from line of increments down to base of ordinates, exactly 1in., which is correct. It is also useful to engineers to know how much the catenary length exceeds the length of span for any temperature between 22deg. F. and 77deg. F. This can be at once learnt from diagram 6, by measuring from the line of expansion-increments down to the curve marked "Limit of Span." For example, the catenary at 50deg. F. is thus found to measure about 1$\frac{1}{10}$in. longer than 300ft. span, which is correct. Thus the engineer may read at once, off this diagram 6, the stresses, dips, expansions, and catenary lengths, due to any given temperatures, between 22deg. F. and 77deg. F., for a 100lb. copper wire, strained to quarter breaking tension of 330lb. and a span of 100 yards. It would be easy to prepare similar diagrams for any spans and qualities and conditions of wire.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

CHAPTER VII.—*Simple Tests with Indicators (continued).*

(Continued from page 350.)

79. In an insulation test of any line the line wire itself will not be connected to the instrument direct, but generally through a "leading in" wire. As the line is tested through this wire, it is important to see that it is itself well insulated. To do this the end of the leading wire affixed to the line should be disconnected or "freed" for a moment or two while the battery is put on as before and it is observed whether the indicator shows any deflection; if it does, it shows there is a leakage between the leading wire and earth. Since this would falsify the results when the line is tested, allowance must be made for it in the following manner:—Work out the insulation resistance between the leading wire and earth exactly in the manner described for a line. Now, on connecting up the line and measuring its insulation it is evident that instead of obtaining the true insulation of the line we measure the *joint* resistance of the insulation of line and leading wire because these two resistances are connected together in parallel arc. The first resistance measured is that of the leading wire alone, and the second resistance is that of the line and leading wire together. The little calculation to be made in order to derive the true resistance of the line from these two measurements will be easily seen by reference to the conductivity of the respective circuits. It will be remembered that the term conductivity is used to express exactly the opposite property of resistance, Sir William Thomson having introduced the term "mho" for the unit of conductivity, which is taken as the exact reciprocal of one "ohm," and, in fact, is that word (or rather name) spelt backwards. The term, as far as use is concerned, is not in everyone's mouth just yet, the idea of resistance having such a deeply-rooted hold of us all; but the *idea* of conductivity lends itself very conveniently to the consideration of resistances in parallel, for we know that in this combination the total conductivity is simply the sum of the conductivity of each, and the reciprocal of the total conductivity gives the joint resistance of the whole. In the above case we require to know the resistance of the line alone. Now we can easily find the *conductivity* of the line alone by subtracting the conductivity of the leading wire from that of the leading wire and line. The resistance of the line alone is then found by taking the reciprocal of its conductivity. *Example*:—A line wire is connected by a leading wire to a testing room, its other end being "freed," and a test for insulation gives 350,000 ohms; the leading wire is then disconnected where it joins the line, and

Digitized by Google

a second test gives one megohm (10^6 ohms). What is the insulation resistance of the line?

$$\text{Conductivity of line and leading wire} = \frac{1}{\cdot 35 \times 10^6} \text{ mhos.}$$

$$\text{Conductivity of leading wire alone} = \frac{1}{10^6} \quad "$$

$$\text{Therefore, conductivity of line alone} = \frac{1}{\cdot 35 \times 10^6} - \frac{1}{10^6} \quad "$$

$$= \frac{\cdot 65}{\cdot 35 \times 10^6} = \frac{13}{7 \times 10^6}$$

and the resistance of the line is the reciprocal of its conductivity—viz., $\frac{7 \times 10^6}{13} = 538{,}000$ ohms.

80. The points in which improvements have been attempted in the construction of the current indicator or detector have been chiefly the following:—

1. Reduction of the friction on the moving needle to a minimum, doing away with irregularities in the relation between currents and deflections, due to variation of friction, and rendering the instrument more sensitive.
2. Protection of bearings and needle spindle points or pivot points while the instrument is subjected to shaking and otherwise knocking about in transit.
3. Best method of winding the coil to give maximum effect when occupying a given volume.
4. Facility of reading quickly and accurately the deflections.
5. Easy accessibility of all parts of the apparatus for purposes of cleaning or adjustment, if required.
6. Sensitiveness, or variation of deflection for slight changes in the current.

An instrument combining portability with the above conditions being a great requisition to the ordinary battery and

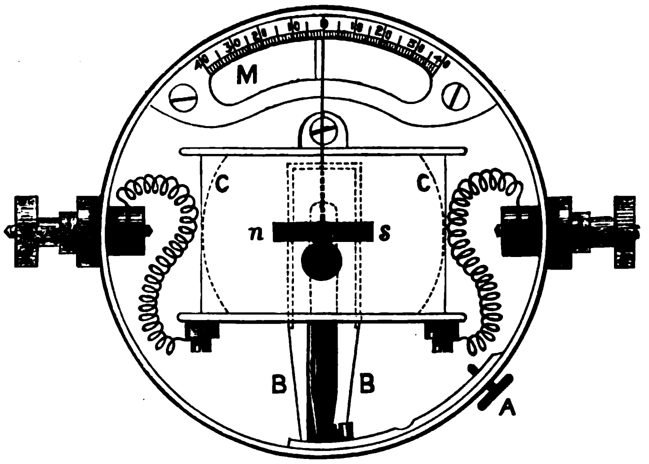


Fig. 44.

line testing at the General Post Office, a great deal of attention has been brought to bear upon its improvement by Mr. Preece and Mr. Kempe, in conjunction with Mr. Eden, with the result that a "standard" form has now been evolved as the "survival of the fittest" of all their experiments and trials. This instrument is illustrated in plan in Fig. 44, and in elevation in Fig. 45, the cover in this figure being removed and the needle support withdrawn from inside the coil. The needle itself is shown in Fig. 46, and is a very light steel magnet of the shape *n s*, to which is affixed a brass cap, C, holding at its centre the sapphire cap which rests on the pivot point when the needle is in position. The pointer *p*, at the extremity of which the readings are taken, is a rigid and light strip of ebonite fixed at right angles to the needle, and the weight *w* of the same material serves to balance the needle in a horizontal position. In both the other figures the movable brass slide B, on which is fixed the upright steel pivot to carry the needle, is shown. This slide containing the needle is easily inserted into or withdrawn from the coil, its movement being kept rigidly in one direction by its bevelled edges sliding in guide grooves cut along the interior of the brass bobbin. A slight projection on the slide seen in the figure fixes the limit to which the slide can be pushed into the coil, and insures the needle always being in the centre of the coil. The steel pivot point is finished with great care, being carefully examined under the microscope during manufacture, the sides converging towards the point in as nearly as possible the curve of a parabola. Protection of the point when the instrument is not in use is secured by raising the needle from off it by means of the lever

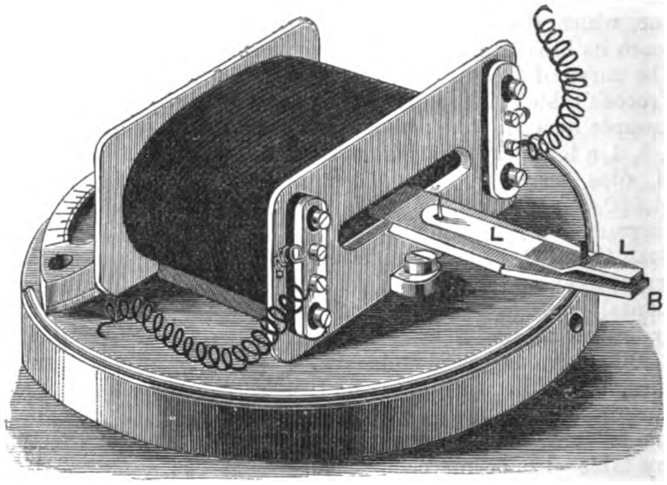

Fig. 45.

L L. It will be easily seen that by depressing the short end of this lever the other end lifts the needle off the pivot, and it is arranged that the downward play of the short end (effected by moving the screw head A sideways to the left) shall be just sufficient to raise the needle through the requisite distance to bring its cap into close contact with the top of the interior of the brass bobbin, thus preserving it completely from move-

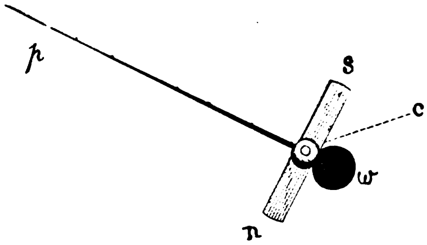

Fig. 46.

ment during transit. The dotted lines in the centre of the coil in Fig. 44 show the needle mounted in position. Its point then rests over the divided scale, attached to which is a mirror, M, the purpose of which in instruments of this class is to avoid the error of "parallax" while reading the deflections. This error will always be more or less introduced according as the point of the needle is at a greater or less distance from the scale when the direction of the line of sight from the eye of the observer to the needle is not always constant. By means of the mirror (attached to all accurate instruments), the reflected image of the needle is visible in the mirror, and the reading on the scale is not taken until the needle is seen to exactly cover its own reflection therein. In order to throw as much light as possible on the scale and needle, a glass window is let into the side of the brass cover opposite the scale, and the top of the cover being of glass, there is every possible facility for very accurate readings. It is seen, therefore, that conditions 1, 2, and 4 are complied with. The third condition is carried out by Mr. C. J. Simmons, of London, the maker of the instrument, by "grading" the wire composing the coil, and giving the outside contour of the coil the shape of the curve indicated by the dotted

Digitized by Google

lines *c c*. When the size of the coil—that is, the space to be occupied by the wire—and its required resistance have been once fixed upon, it has been pointed out by Sir William Thomson that the maximum magnetic effect, or, what is the same thing with the same current strength, the maximum number of *turns* of wire, can be wound into the allotted space when the wire is graded in sections of different diameter. That is, the winding is commenced nearest to the needle by fine wire, a certain portion of the available space being filled up with this winding. Then a wire of larger diameter is jointed on to this and the winding continued. This is done for three or four different sizes of wire, all being calculated at first so as to add up to the required resistance when completely wound on. In this instrument the wire is graded three times, the final resistance being 800 ohms. The shape of the exterior of the coil is also a matter of consideration, and the same authority gives it as the most effective winding for the coil of a current indicator or galvanometer when the greatest number of turns of the wire are wound near to the needle when at rest—that is, at right angles to the axis of the coil—the shape of the curve itself being accurately expressed for coils whose turns of wire are in circles by a mathematical equation.

The fifth condition is ensured very effectively as regards the accessibility of the needle, this having already been shown. The ends of the coil go to separate terminals on an insulated brass plate, two other terminals on which serve to connect a short spiral of thick wire to the instrument terminals, in the usual way. The finish of the instrument, as turned out by Mr. Simmons, is excellent, the G.P.O. having relegated all their old astatic forms of indicator to this maker to convert into the "approved converted form," with the parts somewhat similar to the above. The instrument which has been described above is not "astatic." An instrument is said to be astatic when it is provided with two parallel needles mounted on one spindle, and turning together, one being inside the coil and the other outside, and the opposite poles of the two needles pointing the same way. By this device the controlling force of the earth's magnetic field upon the needle which tends to draw it towards the magnetic meridian when it is deflected away from it by a current is almost entirely done away with, only sufficient difference between the magnetic moments of the two needles existing necessarily in order to keep the needles at zero when no current is passing through the instrument coil. The writer has taken a "calibration curve" of the instrument described above, and finds that there is a "straight line law," or proportionality, between currents and corresponding deflections up to an angle of 27deg., this being nearly the whole length of movement of the needle, which, owing to the construction of the coil, is limited in its movement to 35deg. In the following chapter the calibration of current indicators will be considered, with the plotting of curves exhibiting the relations between the strength of the current and the angular movement of the needle.

(To be continued.)

SAFETY LAMPS IN COLLIERIES.*

BY W. H. PREECE, F.R.S.

On a fine summer's day the sun expends an average of one horse-power on every 30 square feet of the earth's surface in this latitude, or 1,450 horse power per acre. This great gift of energy is neither utilised nor stored by man at present, though Nature presents us with some of it in waterfalls and flowing streams. The sun itself has been more generous. Ages upon ages ago it shone with resplendent glory on a grand luxuriant flora of a uniform but flowerless character in a climate warm and damp. England formed part of a tropical jungle or swamp, where grasses, mosses, ferns and sedges, *coniferæ*, *araucariæ*, *equisetæ*, *sigillariæ* grew and flourished, perished and fell *in situ*, to be covered up by following geological formations and compressed into those grand seams of coal that form now the principal source of England's greatness and wealth. If language be fossil poetry and words condensed history, then coal may be derived from *coelum* or *κοιλος*, and imply a Heaven-sent gift.

The first authentic account of coal digging dates from the reign of Henry III., when Newcastle sent its first cargoes by sea to London, and thus gave the mineral the name of *sea-coal*. Early records of the output of coal are wanting.

In 1700 it was 2,614,000 tons.
In 1800 it was 10,000,000 tons.
In 1850 it reached 42,000,000 tons.
In 1886 it reached 157,518,482 tons.

A ton of coal occupies very nearly a cubic yard of space. Hence this quantity of coal, if placed in Hyde Park, would form a mountain as high as Snowdon, and if erected as a wall around the coast line of Great Britain, it would be 6ft. wide and 30ft. high. It would form a girdle round the world 3ft. wide and 12ft. high. We extract from the earth twenty times more energy than the sun can possibly restore to it by the growth of forest, and we are gradually but surely tending towards the time when this store of power, heat and light will be exhausted, when our busy hives of industry must seek other shores, and when England will perhaps become a summer resort for a wealthy Anglo-Saxon race occupying other quarters of the globe.

Coal is not only, like knowledge, power, but, like the precious metals, it is wealth. The average price of coal at the pit's mouth in 1886 was 5s. per ton, and thus its total value was £40,000,000, but when we consider the average price paid for it, we must double, if not treble, this lump sum. The number of collieries open was about 3,500, and since it costs £100,000 to open a colliery 2,000ft. deep, and when we think of the railways, the canals, the ships, the shops, the marts employed for its transit and its distribution, we can only conclude that the capital embarked in this industry must equal, if not exceed, the National Debt.

The hewing and raising of coal is unquestionably a dangerous occupation. "The price of coal is pit-men's lives," said an old collier to George Stephenson. 520,000 persons are employed in our collieries, and the output per person is 308 tons. 953 persons met their deaths in 1886; but it is satisfactory to know that a miner's life is more than twice as safe now as it was thirty years ago.

The number of persons employed per death was—

In 1856	242
In 1886	545

The number of tons raised per life lost was—

In 1856	64,700
In 1886	188,800

Most people, if asked what was the principal cause of this loss of nearly 1,000 lives, would answer explosion of fire-damp, but this would not be true. The principal cause of accident is falls of roof and sides. In 1886 there were from—

Falls of roof and sides	461 deaths.
Explosions	129 „
Trams and tubs	81 „
Miscellaneous	282 „

Thus falls of roof form 41 per cent. of the whole, and explosions 23 per cent.

Explosions attract immense attention, from their publicity and their appalling suddenness and magnitude. It is dreadful to take up a morning paper and read of 268 fellow creatures engulfed, as at Abercarne in 1878, or 164 at Seaham in 1880; but the daily and steady loss of life by ones and by twos fails to get chronicled, and passes unheeded by with the very great majority of the 20,000 violent deaths that occur in these islands every year.

In order that you may see how coal is won and hewed and raised, how dangers are incurred and surmounted, I will take you into a coal mine—one of the Cannock Chase Collieries of Staffordshire—by aid of a beautiful series of photographs, taken by means of magnesium light by my friend Mr. Arthur Sopwith, the eminent manager of those mines.

[A series of 27 photographs were exhibited.]

* Paper read before the Royal Institution, February 10th, 1888.

Digitized by Google

I have shown you most of the operations connected with the winning and working of coal; some of the risks the miner incurs; some of the troubles arising from gas, water, and falling roofs; and one of the modes of producing ventilation—the chief prevention of accident. What our mines could have been in days gone by it is impossible to conceive; now mechanical appliances are so admirable that many mines are as perfectly ventilated as our homes. The temperature below ground is so uniform—50deg. F. at 50ft., and rising 1deg. for each 55ft.—the formations sometimes so dry, that I have actually heard it proposed to establish a sanitorium for consumptive patients underground, lighted by electricity, and supplied with every luxury.

All mines are required to have two shafts—one the *intake* or down-cast, the other the *return* or up-cast, and as the workings are so interlaced with ways and roads, doors are inserted here and there to direct the current, anemometers are used to measure its rate of flow, and any ordinary inroad of gas is swiftly swept away. Fire-damp, or pit gas, is marsh gas ($C H_4$). It oozes out gently from the exposed seam, or sometimes it bursts out through some fissure with great force, forming what are called "blowers." If it be mixed with air, in the proportion of from 5 to 9 per cent. of gas, it becomes highly explosive, and is the prime cause of those fearful disasters that have made coal mining so terrible.

In gasless mines candles always have been and still are used, but in early days, in foul places, men had frequently to work in the dark, or to be content with the feeble illumination of the phosphorescence of decaying fish. It is remarkable how the eye adapts itself to feeble light, and in the Cimmerian darkness of a coal mine even phosphorescence has a useful illuminating effect. In many places they used the *steel mill*, a disc of steel rotated rapidly against flint, giving light by the shower of sparks thrown down. It is most remarkable that no scientific thought was devoted to this subject until 1815. In 1813 Dr. Clanny, of Newcastle, had devised a very poor lamp, the air to support which was driven by bellows through water; but in 1815 Sir Humphrey Davy devoted his powerful mind and skilful hands to solve the question, and speedily invented in this very Institution his immortal safety lamp. It is a remarkable coincidence that in the same month another powerful but untutored mind, by strong observant powers and pure mechanical reasoning, had arrived at very nearly the same result; and even to this day the affectionate remembrance and name of the eminent Northumbrian brakesman, George Stephenson, is maintained by the use of the "Geordie," in his old home, the Killingworth Colliery.

Davy's classical paper was read before the Royal Society, on November 11, 1815, and was entitled "On the Fire-Damp of Coal Mines; and on Methods of Lighting the Mine so as to Prevent Explosion." He showed that flame would not pass through small tubes and apertures, and how in comparatively still air, however charged with gas, a wire gauze surrounding the flame so reduced the temperature by radiation that explosion was impossible. Ingress of air and egress of products of combustion are resisted. He showed that a flame so protected gave immediate intimation of the presence of gas by burning dimly, and by becoming capped with a blue flame, or *aureole*, that though the wire gauze became redhot, it still radiated away the heat sufficiently to prevent its reaching the temperature point of explosion. He also pointed out, which has been strangely neglected, until enforced recently by the Royal Commissioners on Accidents in Mines, that it failed to act in a current of air, but that this effect of currents could be diminished by shielding or protecting the inlet of air.

The main principle discovered by Davy is the basis of all safety lamps burning oil or spirit, but several departures in form have been proposed at different times. The "Geordie" is in reality a Davy lamp with a glass shield. The "Jack" lamp is a Davy in a tin can. The "Clanny" is a Davy lamp with the flame portion surrounded by a thick glass cylinder to increase the emission of light, and now with a bonnet or shield to protect it from currents of air. The "Mueseler," or Belgian type, is a "Clanny" with a central metallic cone acting as a funnel to increase the draught, and therefore the light. The "Marsaut," or the French type, is a bonneted or protected "Clanny," with two and three gauzes added to increase the security. The number of lamps is legion. A new intake here, a fresh egress there, a new direction to the currents of air feeding the flame, a change in the form or character of the wick, a lock, a different form of pricker, a shut-off or extinguisher (automatic or manual), is quite sufficient to justify a new patent and a new name. The Royal Commission experimented upon 250 different kinds of lamps.

Since the commencement of the year a new Act has come into force rendering it unlawful to use the plain "Davy," "Stephenson," or "Clanny" lamp in mines where safety lamps are necessary. They must be shielded, and great numbers are being converted into bonneted "Marsauts" and "Mueselers." They are also being constructed to burn the best vegetable oil (rape or colza), to which one-third mineral oil is added, as recommended by the Royal Commission, to enhance the light-giving power of the lamp. These converted lamps have baffled all attempts to explode them in currents of explosive gases of very high velocity, and under the most rigid tests.

There are several objections to these oil lamps. They go out, or are put out when danger exists; they render that most important and essential duty, examination of the roof, difficult and insufficient. If they become extinguished by accident or design, much time is necessarily wasted in getting them relighted, an operation that must be done at or near the shaft, perhaps two miles away from the working face, and which therefore reduces the output of coal and the earnings of the collier. The light they give, even at the best, is very small—about one-third to half of a candle.

There are several dangers present. The Royal Commission said:—"The source of light within the lamp should be unable under any circumstance at all likely to occur in working coal to cause the ignition of an inflammable mixture of fire-damp and air, even when this is passing at a high velocity." But glasses break by water, heat, falling coal, and accident. Joints get loose and bad even when protected by asbestos washers. They prove a constant temptation to the thoughtless and callous to get a light. The perfect light does not exist at present, but while these mechanical lamps are very excellent in their way, electricity seems likely to step in and supply their deficiencies and fill a decided want. An electric lamp can be made to give any desired amount of light, and anything between half a candle and a candle seems easily attainable, while such a light can be maintained steady and bright in explosive gases and in strong currents of air. They are simple in construction, easy of inspection; they are not likely to be extinguished in handling like the Mueseler; but they do not act as detector of the presence of gas, and they might explode gas if their protecting glass shield were accidentally broken.

It is remarkable that Davy himself in 1815 experimented with an arc lamp in a closed vessel of glass, but it was not until 1865 that a practical lamp was proposed for collieries. Dumas and Benoit used a small Geissler tube illuminated by sparks from an induction coil and excited by a primary battery; but it was heavy—it was a kind of knapsack to be carried on the back, and it met with no success.

Mr. Swan has been more successful. The great success of the glow lamp, in the introduction of which he has played so prominent a part, and the perfection of the secondary battery have enabled him to produce a lamp that compares in weight and size and light with the best mechanical lamp. Eight hundred of these lamps are in constant use in the National Colliery in the Rhondda Valley in South Wales, and 1,600 more are on order for the Risca and Abercarne Collieries belonging to Messrs. Watts, Ward and Co. They are giving great satisfaction. A collier told me that the electric light was "as good as the moon." The lamp batteries are charged a great number at a time in blocks at the pit bank.

Mr. Pitkin has also been very successful in making light portable lamps, and they have been practically used at Cannock Chase and at the Tyldesley Collieries in Lancashire.

The "Sun" lamp is another very promising form, worked by secondary battery. It is light—3lbs. 12oz.; it gives

Digitized by Google

1¼ candle, and this is maintained for 10 hours. Secondary cells usually require about 12 hours' charge to emit a 10-hour discharge, but this cell will give a 10-hour discharge with 4 hours' charge. It is fitted with a safety appliance—a plan patented by Mr. Sennett in 1882—by which the lamp is automatically switched out the instant that the outer protecting glass is broken or cracked, so that contact between the hot filament of the lamp and the explosive gas is prevented. This safety appliance has been tested by Mr. Rhodes at the Aldwarcke Colliery in actual explosive mixtures.

Many efforts have been made to introduce primary batteries for the same purpose, but up to the present moment I have seen only one—the Schanschieff—which, in efficiency, lightness, and economy, comes up to the requirements of a safety lamp. A primary has this advantage over a secondary battery—that it is charged at once by an operation as simple as that of trimming a Davy. To trim a Davy means thorough cleaning, inserting a fresh wick, pouring in new oil. A primary battery means pouring out old and pouring in fresh solution.

Occasionally zinc requires renewal, but all these operations are within the intelligence of the collier, and the lamps need not go to the surface. The simplicity of the operation has distinct merits of its own that compensate for the extra cost of the materials used.

The chief charm of the electric lamp is not the greater light that it gives but the power it gives the viewer to examine the roofs of the ways and workings; it is so extremely portable and handy; it can be put anywhere; the battery can be placed on the ground or suspended by a spike to a tree, and the lamp can be fixed in the cap or around the waist; it can be put anywhere and used anyhow.

Mr. Sopwith, at Cannock Chase, has been taking heavy batteries to the working face, and using bright 8-candle lamps in reflectors, so as to illuminate the working face with a light which in that region is comparable to daylight. The men are charmed with it.

The chief defects of the electric lamps are their fragility, the liability of the carbon filament to break, the weight of the battery, and the absence of gas detection; and these defects have been very much enhanced by imperfect construction and injudicious details. Electricians have not spent sufficient time in the lower regions, and practical colliers have no time to go to the laboratory. When the two professions are properly amalgamated we shall very likely obtain the true safety lamp.

The electric lamp is not a fire-damp detector, but an electrical appliance is easily added. Liveing and Swan have done this; but it is doubtful whether a more efficient detector than the Davy exists, and whether an apparatus that is so thoroughly understood, and so thoroughly practical, will be superseded for a purpose for which it seems so eminently adapted.

I cannot conclude, especially in this place, with more pregnant words than Davy's own:—"The gratification of the love of knowledge is delightful to every refined mind; but a much higher motive is offered in indulging in it when that knowledge is felt to be practical power, and when that power may be applied to lessen the miseries or increase the comforts of our fellow creatures."

INSTITUTION OF MECHANICAL ENGINEERS.

THE POSITION AND PROSPECTS OF ELECTRICITY AS APPLIED TO ENGINEERING.

BY MR. W. GEIPEL

(Concluded from page 357.)

Storage Batteries.—Storage batteries on the car have not as yet been much used, though many experiments have been made from time to time. The problem was first attempted by Mr. Reckenzaun, who has done much to perfect the plan.* The difficulty is that, if the accumulators are made light, their depreciation is high, while if they are constructed with a thoroughly serviceable make of cell, their weight is very great. The first cost of the cells is also somewhat prohibitive, and their depreciation is high. A trial of this plan on a practical scale is now being made by Mr. Elieson on the North Metropolitan Tramway in London.* The storage cells are placed on a separate locomotive car. The motor turns itself round on an upright pivot by means of a bevel wheel on the armature shaft, gearing with a circular rack fixed on the floor of the car, and the revolution of the motor is transmitted to the axle of the car through mitre gear. The plan has been unsuccessful in the past, owing to the use of inefficient motors and gear, which require of course an increased size of battery in proportion to their inefficiency; the imperfection of the secondary batteries employed, as pointed out, has also prohibited success. With motors, speed-reducing gear and secondary batteries all improved, the experiments now being made bid fair to demonstrate the successful working of tramways by electricity in crowded thoroughfares.

* See *Electrician*, Sept. 23rd, 1887, p. 426.

Ordinary Rails as Conductors.—The short electric railway of Mr. Volk at Brighton† on this system is interesting as being one of the earliest in use in this country. The expenses amount to 2d. per car-mile, being made up as follows:—

	Pence.
Gas for engine	1·11
Wages	0·70
Oil and waste	0·07
Repair	0·12
Total per car-mile	2·00

The total car-miles per annum are stated to be 47,000, and the depreciation at 10 per cent. on the £3,000 cost of construction is, therefore, equal to 1½d. per car-mile, thus bringing up the total cost to 3½ pence per car mile. Several similar railways are now working or contemplated in seaside towns.

Cost of Working.—From these instances it will be seen that, taking into consideration the fact that the machines here employed are not so efficient as those now being made, an electric tramway may be worked for about threepence per car-mile, and as the cost of horses is from sevenpence to ninepence per car-mile, the importance of electric propulsion for tramcars and short railways is very evident. At the Antwerp Exhibition in 1885, when electric locomotion was beginning to receive consideration in its commercial aspect, a series of trials extending over four months on five different kinds of tramway motors resulted in the first place being assigned to the electric car, in competition with the four following plans:—The Krauss and the Wilkinson locomotives separated from the car, the Rowan engine and the car combined, and the Beaumont compressed-air car. The results of these trials are given in the following table:—

Trials of Tramway Motors at Antwerp Exhibition, 1885.

Description of motor		Electric	Rowan.	Wilkinson.	Krauss.	Compressed Air.
Train-miles run, total		2,359	2,617	2,473	2,458	2,259
Consumption of fuel.	total......lbs.	14,786	14,498	22,000	22,726	90,420
	per train-mile ...lbs.	6·16	5·42	8·82	9·10	39·48

Notwithstanding that the use of electricity for heavy railway traffic has been predicted, the author thinks that, so long as the electricity is generated by dynamos driven by steam engines, steam locomotives will not be discarded in favour of electricity for long distances. But for light railways and suburban lines, underground or overhead, where the use of a steam engine is a nuisance, there can be little doubt that electricity must be largely adopted in the immediate future, as the number of such railways already constructed and in course of planning is now between one and two hundred

Telpherage.—The plan of transporting material in skips on overhead wire-ropes by means of electricity, introduced under this name by the late Prof. Fleeming Jenkin,‡ of Edinburgh, has not so great a field for its use in this country as it may have in less populous regions, because our roads are good, and railways generally near at hand, and we have abundance of water carriage. But in places where material has to be conveyed across hilly districts or over bad roads to the railway or water it will be found more useful. It has been employed with considerable success for the past two years at Glynde§ near Lewes for transporting clay to the railway over a distance of 1,600 yards; 270 tons are carried weekly at 7½d. per ton. In our larger cities a modification of this plan might advantageously be applied to alleviate the heavy

Digitized by Google

street traffic. In the place of wire-ropes, stiff girders might be used, the cars being suspended from wheels running along a rail or rails fixed on the girder. Such a railway would be economically constructed, in comparison at least with the expense of constructing an underground railway; and it would not have any great effect in obstructing the light from the streets, as is the case with elevated railroads for steam locomotives.

III. Electric Lighting.

Of the four branches of electric engineering dealt with in this paper, electric lighting is the one which up to the present has received most attention, called forth the largest outlay of capital, and produced the most beneficial results, if not to so great extent in this as in other countries.

In incandescent lighting, the cost of distribution is still heavy, though by increasing the electromotive force and the efficiency of lamps it is being much reduced. In arc lighting, the difficulty of subdividing and of reducing the amount of light given by one arc lamp renders it expensive for general out-door street illumination, as compared with the present low prices of gas and oil. For the lighting of main streets and railway stations, or other places where a concentrated light is required, the arc light is beyond question far cheaper than gas; and its cost per candle-power is but a very small fraction of that of gas. As the use of electric lighting extends, the cost of working becomes reduced; installations which four years ago cost fourpence per arc lamp per hour are now costing only twopence. The chief saving has been in the items of carbons and attendance, though the increased efficiency and durability of the apparatus have also greatly contributed to the reduction; four years ago 11mm. or 0·43in. hard carbons cost 4d. per foot; they can now be obtained for 1½d. per foot, or less than one-third.

The following figures supplied by the North British Railway respecting the actual cost of working their electric lights at the Waverley Station, Edinburgh, are interesting as showing how much cheaper it is becoming. The installation is worked by their own staff, and consists now of forty Brush arc lamps, supplied with a current of 10 amperes by a No. 8 Brush dynamo, which is driven by a semi-fixed engine:—

July to December, 1884, thirty-three arc lamps, 41,884 lamp-hours.

Wages	£165	13	9
Repairs	47	2	6
Carbons	125	15	11
Coal	65	19	11
Oil, stores, &c.	27	15	0
Interest and depreciation at 10 per cent.	52	2	2
Equal to 2·77 pence per lamp-hour.	£484	9	3

July to December 1886, thirty-nine arc lamps, 55,068 lamp-hours.

Wages	£195	17	6
Repairs	78	9	6
Carbons	62	17	3
Coal	23	14	1
Oil, stores, &c.	8	15	2
Interest and depreciation	41	10	6
Equal to 1·79 penny per lamp-hour	£411	4	0

In conjunction with these arc lamps they are running 148 Brush Victoria incandescent lamps, distributed in the refreshment and waiting rooms, and throughout the whole of the suburban station. For these the total number of lamp-hours for the half-year was 171,251, and the cost was £83. 9s. 9d., including all contingencies, equal to 0·12 penny per lamp-hour. There were 113 lamps renewed, which shows an average life per lamp of 1,515 hours.

Local Conditions.—The cost of incandescent lighting is especially variable, and affected by the local conditions of the installation. The chief of these are (*a*) the average number of hours of lighting each lamp, and (*b*) the average distance of the lamps from the generating station. Where the conditions are favourable, incandescent lighting can already compete with gas; and in a number of installations which have been superintended by the author a large saving is being effected. The following figures kindly supplied by Messrs. George Jaeger and Son show that the yearly cost of lighting their sugar refinery at Leith has been reduced from £347 with gas to £204 with incandescent lamps. The average life of the lamps is about 1,400 hours each. The installation consists of 180 Brush Victoria lamps of 17 and 10 candle-power, supplied by a self-regulating Victoria dynamo, which is driven off the shaft that drives the centrifugal drying machines. The dynamo has been running night and day since it was started two years ago, without failure. It is started on Monday morning, and runs continuously without stoppage till the following Saturday afternoon.

Previous average cost of gas lighting per annum.	£332	13	4			
Part of plumber's time	15	0	0			
				£347	13	4

Cost of Electric light, May, 1886, to May, 1887.

Lamp renewals	£46	9	8			
Oil, waste, sundries	17	5	0			
Coal at 3lb. per horse-power per hour, 40 tons at 6s.	12	0	0			
Repairs, including men's time attending dynamo	36	5	3			
Depreciation at 10 per cent.	33	16	0			
Gas consumed on Sundays, and when engine is standing	58	4	5	204	0	4
Saving per annum by electric lighting				£143	13	0

In the United States there is hardly a city or town of 20,000 inhabitants which has not a central station for arc or incandescent lamps; and many towns of 3,000 or 4,000 are supporting them also. On the Continent large central stations for electric lighting are already in operation in competition with gas; but there the price of gas is generally two or three times what it is in this country.

If the power is to be generated by dynamos and used direct, the cost of distribution on a large scale will probably never be reduced as low as with the existing gas supply, seeing that an efficiency of 95 per cent. can now be obtained with the dynamo, and that steam engines are not likely to be materially improved. It is therefore in the lamps that improvement is to be looked for, by making them with a higher resistance and greater efficiency.

Transformers.—These are at present receiving a large amount of attention. By their means small high-tension currents of electricity, sent from a distant generating station along a small conductor with a comparatively small percentage of loss, can then be converted into large low-tension currents for the supply of ordinary incandescent lamps. In some arrangements of these transformers the loss in conversion is not more than 5 per cent. Unfortunately the alternating system, which has thus far been adopted, cannot be used with satisfaction for driving motors doing practical work or for charging storage batteries. The continuous current transformer has certainly the advantage in respect to the supply of power and to the charging of storage batteries; but it is a question whether the disadvantage of having to keep it continually in motion will enable it in town lighting to compete with the alternate-current transformer. The latter is employed in the Grosvenor Gallery central station in London. Some idea of its importance may be formed from the fact that the Westinghouse Company have already in America over 100,000 lamps at work on this system, although it is not yet so much as two years since they adopted it. Notwithstanding that the use of transformers enables a great saving in copper to be effected, more especially where the lamps are scattered, as in suburban districts, yet it is to be remembered that the insulation of underground conductors forms a very important item in their total cost. The installations already at work are all worked with overhead conductors, with the one exception at Eastbourne; so far as the author is aware there are no practical data to establish the general applicability of the transformer system for the lighting of large and thickly populated towns where underground conductors may alone be tolerated.

Secondary batteries charged in series by a high-tension current and discharged in parallel circuit have been tried experimentally; but their practical application is not known to the author. At the same time, now that transformers are becoming more used, strenuous efforts are being made to introduce this system of secondary batteries, and if it can once be demonstrated to be economical, there can be little doubt that it would have a large field of application. Its great merit is of course the reduction of risk of the light failing.

It should be borne in mind by electric light companies that the supply of incandescent lamps is not to be their only source of revenue; but as already pointed out, the supply of current should be of such a nature that it may be employed for as many purposes as possible. By the use of efficient boilers and engines and properly constructed continuous-current dynamos, a central station can be so constructed as to be no nuisance whatever, provided proper precaution be taken in selecting the site. In large towns it will not be necessary to extend the conductors very far before a demand will be met with sufficient for occupying an engine large enough to be economical. Above a certain size the cost of working a steam engine becomes practically constant for any increase in size; so that, instead of working from one large central station over a very large area, it is found better to work from smaller stations over smaller areas. The cost of attendance will thereby be increased to only a small extent, because one man cannot fire more than two boilers; therefore, when more boilers are required, it is preferable to work them at another station with another fireman. At Leamington an extensive central station is now at work, and the cost of the undertaking is about £30,000. The Bradford Corporation have recently voted a sum of £15,000 for erecting a central station in their town. Both of these are instances of direct supply, without transformers or secondary batteries.

IV. ELECTRIC METALLURGY.

This branch of electrical engineering bids fair to become speedily of the highest interest to engineers. The electro-chemical separation of ores on a commercial scale by the electric furnace has but recently been put to the test, chiefly in obtaining aluminium from corundum, its richest ore. Sir William Siemens first turned his attention to the subject, but his death occurred before he had perfected his invention. It was taken up by Messrs. Cowles, who with the assistance of Prof. Mabery have devised a furnace, in which by the passage of powerful currents the refractory ore is successfully reduced.* The furnace is built of fire-brick, and lined with powdered charcoal to withstand the intense heat. It is in the form of a box, 5ft. long, 12in. wide, and 15in. deep. Current is conducted through the walls and into the ore by means of a number of carbon rods 3in. diameter, and from 2 to 3ft. long. The positive and negative carbons are introduced from opposite ends, and nearly meet in the centre. The ore, mixed with charcoal and granulated copper, is put in so as completely to surround and cover the carbon. The furnace thus charged is closed with a layer of charcoal and a lid lined with firebrick; without the protection of some such refractory material as charcoal the intense heat causes the firebricks to run. When the furnace is ready, the current with an electromotive force of 50 volts is turned on, and is gradually increased up to some thousands of amperes. In a few minutes the metal is melted around the electrodes; and these are then moved farther apart, until the current passes through the entire charge, and the whole is in a molten condition; the corundum becomes gradually deoxidised, the aluminium combining with the copper, while the oxygen with the carbon escapes as carbonic oxide; about five hours suffice to complete the reduction. Current was supplied by large Brush dynamos, which were specially constructed for the work, and is capable of giving out 300,000 watts, or over 400 electrical horsepower. Its weight is nearly 10 tons; 5,424lb. of copper are wound on the field-magnets, while the armature has 825lb. of copper on it. Works already in operation at Lockport, U.S., have a capacity of 6,000lb. per day, and the cost of the aluminium-bronze so made is expected to be less than 1s. 8d. per lb., while Mr. Cowles anticipates the price being reduced to 8d. per lb. Works have also been started at Stoke-on-Trent, where a 500 horse-power dynamo has been fixed for generating the current; the potential is 60 volts.

Another electric furnace has been devised by Dr. Kleiner, of Zurich, in which cryolite, a double fluoride of sodium and aluminium, is similarly treated.

When it is remembered that the metal aluminium, in addition to many other good qualities, possesses great strength with only one-third the weight of iron, the importance of obtaining it at a reasonable cost will be readily appreciated; it would undoubtedly cause a great revolution in engineering construction.

The process of welding by electricity, introduced by Prof. Elihu Thomson,† is similarly based upon the passage of a powerful current between two electrodes. In this case the two pieces of metal to be welded form the electrodes; they are brought together into close contact, and as soon as the current is sent through the joint its resistance causes intense heat until the weld is perfectly completed. The process is almost instantaneous, and the heating occurs only at the joint; tempered steel can thus be welded without in the least affecting its hardness.

Another plan of electric welding has been introduced at St. Petersburg by Dr. Benardos, in which the heat necessary for fusion is caused by an arc. The current is conducted to the weld by means of a carbon rod, which is connected by a flexible cable with the positive terminal of a dynamo or battery, while the metal to be welded is connected with the negative terminal. The action of the arc set up by the flow of current from the carbon to the metal may be likened to that of the blow-pipe flame, except that the heating is more intense and sudden, and is therefore more local. The reducing action brought to bear on the metal keeps it clean and unoxidised.

[We shall next week give a full report of the discussion on this paper.]

† See *Electrician*, Sept. 17th, 1886, p. 392.

Errata.—We are requested by Mr. Kapp to correct two typographical errors in the proof of his paper read last Thursday at the Society of Telegraph-Engineers and Electricians. These errors occur in our reprint on page 339 of the last issue in the list of symbols. Instead of $e = \sqrt{E}$, read $e = \frac{E}{\sqrt{2}}$, and instead of $i = \sqrt{I}$, read $i = \frac{I}{\sqrt{2}}$. The exponent in the formula for E lower down the column should be $^{-8}$, and not $^{-3}$.

"THE ELECTRICIAN" *can be obtained in America from* D. VAN NOSTRAND, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

THE ELECTRICIANS' DIRECTORY.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY IS NOW READY.

NOW READY.

Volume XIX. of "The Electrician," strongly bound in cloth, is NOW READY, price Ten Shillings and Sixpence.

Cases for binding "The Electrician," price Two Shillings, Now Ready.

THE ATLANTIC CABLE RATES.

The announcement which we were able to make a short time ago that a conference of the Atlantic Cable Companies was about to be convened for the purpose of agreeing upon a uniform tariff has been confirmed by what has transpired at the half-yearly meetings held in the interval. At the Anglo-American meeting last week the chairman, although not very sanguine as to the result of the proposed gathering, expressed himself favourable to its being held and to the objects it is designed to accomplish. Both at that meeting and at the one previously held by the Direct Cable Company the shareholders were almost unanimously in accord with the directors; and with the exception of a few isolated suggestions for reducing the tariff still lower, for raising it very much higher, or for the adoption of preferential rates—all of which propositions were impracticable and not supported by any considerable body of shareholders—the prevailing opinion seems to have been that the present rate ought no longer to be maintained, and that the time has arrived for a joint arrangement, or at all events an amicable understanding, among all the competing companies to adopt a tariff at once uniform and profitable. The sixpence-a-word rate has been tried for two years over all the cables except one, the exception maintaining an independent rate just twice as high. It is notorious that the first-named rate has not been remunerative; and in spite of allegations to the contrary it is pretty obvious that under the circumstances the higher rate has not been remunerative either. A shilling rate has yet to be tried all round; but with the majority of the cables competing at half price it is not likely that one of them could derive much advantage from the experiment of being singular. Probably they have come to the conclusion that if the higher rate is to have a fair trial it must be adopted by all the competitors alike, and as the dissentient company has nothing to lose, but rather, one would imagine, something to gain by such an agreement, we entertain the belief that it will be shortly arrived at.

Leaving the one doubtful cable company out of account for

Digitized by Google

the moment, its interests and policy being directed exclusively from the other side of the Atlantic, no one can reasonably urge that the English companies and their allies are not perfectly justified in the action they are contemplating. Whether the sixpenny rate was a fighting rate or a financial experiment is a point not now worth discussing. Whatever its object the public have had the advantage of it for two years past, and if the companies have reaped no advantage, but quite the reverse, they might not unfairly lay the blame on the public, if, indeed, blame must be attached to somebody. A great rush of business, as usual, followed immediately on the reduced rate, increasing for a time at a considerable pace; then the increase fell off until, in fact, it showed no more disposition to grow than does the business over lines on which very high rates prevail. This is the usual history of all premature and abnormal reductions—of all reductions, in fact, which are not the natural result of prosperity. The traffic increases, but so does the expenditure; and the result is that the original sacrifice is never recovered, the margin of profit gradually dwinding lower and lower. The one and only conceivable gain to be derived from these fighting experiments is that the area of business may be enlarged and custom secured that will not wholly disappear when the time arrives—as arrive it must—for reverting to normal rates which will pay the proprietors for their investment and risk. Even the shilling rate does not, or did not, answer this description, with several companies competing for traffic insufficient to employ more than two or three of them. But accepting the situation as it stands, and allowing for a permanent increase of telegrams due to the cheaper rate, the adoption of the shilling tariff is an experiment worth trying for a time, on the understanding that it may be further increased if the companies cannot get a living by it.

We have here distinctly asserted the companies' right to frame their own tariffs. This right can be challenged only in one of two ways, either by competition or by monopoly. Of competition in this quarter there has been more than enough to prove that it is simply suicidal. In the long run the public do not gain by it, for they have to support finally more cables than are necessary; in other words, they have to pay rates higher than would be needful if superfluous cables had never been laid. As regards monopoly, if the country had conferred any such privilege on the older Atlantic companies it would have imposed its own conditions; but having elected to allow free competition the public cannot now complain, whatever the consequences may be. And in point of fact we do not believe that the public will complain of any reasonable course which the existing Atlantic cable companies may find it their imperative interests to pursue. The public have always regarded the sixpenny rate as a temporary one, certain to be doubled or trebled when the competitors had adjusted their differences. Moreover, it is perfectly well known that the best customers of Atlantic telegraphy are not in love with cheap rates. What they want is a good service for important transactions; and they are willing to pay a fair price for it—a fact which is proved by one of the companies having kept up its rate, and done a good business at it. The science of coding, too, has risen to such perfection that whatever the rate may be the code user may be trusted to take care of himself. Lastly, the public, so far as Atlantic telegraphy is concerned, is a very limited public—the general public being concerned with it hardly at all. Domestic messages, such as swell enormously the bulk of inland telegraph traffic, and justify the reduction of its tariff to a popular figure, can hardly be said to have any existence in international telegraphy. It is a sufficient condemnation of the sixpence-a-word rate to America to point out that sixpence is the lowest payment for which we can dispatch a telegram across the Thames.

Notwithstanding these obvious and practical considerations, the irrepressible and irresponsible Mr. HENNIKER HEATON has publicly announced his intention of "rendering futile any attempt to raise the charge [for Atlantic telegrams] above 6d. per word." In his letter to *The Times* of Tuesday, where, after modestly insinuating that the "public ought surely to have a voice in the question of cable rates to America," he declares the subject to be of "such vital importance to the people" that he has prepared a letter to the POSTMASTER-GENERAL embracing the whole facts, the publication of which will checkmate these wicked companies. If the "public," as we have above shown, are little concerned with this subject, the "people" are still less so. But how about the POSTMASTER-GENERAL? We suspect that this high official has long ago taken the measure of Mr. HENNIKER HEATON, and will answer him as he deserves—if, indeed, a man who imagines the British POSTMASTER-GENERAL to have anything to do with the Atlantic cables deserves any answer at all. We for our part shall not attempt to argue with this colonial firebrand. He is the member for Canterbury, and if the "people" of that famous but rather somnolent city are interested in Atlantic cables, except as shareholders, the companies no doubt will be glad to hear from them. But he is more particularly a representative of the Australian colony—at all events, of one peculiar element in that colony—holding a brief, as we understand, against the existing cables which connect Australia with the mother country. We would advise him to stick to his brief, and not endanger his fees by interfering in matters for which, except by a spiteful construction, he has no commission whatever, and upon which this letter to *The Times* proves his incompetency to offer an opinion.

THE THERMO-MAGNETIC PROPERTIES OF IRON AND NICKEL.

BY HERBERT TOMLINSON.

The thermo-magnetic properties of iron have been studied even in the early infancy of magnetic science. Gilbert, the physician of Queen Elizabeth, found that a loadstone and piece of iron equally lost their power of affecting the magnetic needle when very hot, and that, whilst the magnetic property returned to the iron after it was cooled, the magnetic virtue of the loadstone was entirely destroyed. Gilbert's observations were confirmed by Brugmans, Boyle, Cavello, Barlow and Bonnycastle, Christie, Ritchie, Erman, Scoresby, Seebeck and others.* Faraday found that a steel magnet lost its permanent magnetism rather suddenly at a temperature a little under the boiling point of almond oil;† it behaved like soft iron till it was raised to an orange-red heat‡, and then it lost its magnetic susceptibility and became indifferent. The temperature at which permanent magnetism was lost varied with the nature and hardness of the steel; pieces of loadstone retained their permanent magnetism until just below visible ignition in the dark,§ but lost their susceptibility at a much lower temperature than iron. Nickel was found to lose its magnetic susceptibility about 330° C. to 340° C.‖ Cobalt was not deprived of its susceptibility at a white heat. The beautifully simple experiments of Dr. Gore have already been described in *The Electrician*,¶ and these have been extended by Baur** and Wassmuth. According to Baur, for

large magnetising forces,* the susceptibility decreases gradually until red heat, and then falls suddenly to a very small value. The same experimenter finds that if a bar be cooled from white heat, the first traces of susceptibility are observed at a very bright red, *the brighter the greater the magnetising force.*

Finally, we have the researches of Berson and Ledeboer, which have been already illustrated in *The Electrician.*†

The writer has, independently of Berson, drawn up thermo-magnetic curves for nickel.‡ These curves relate to *temporary* magnetisation, and in some respects agree with the curve temporary magnetisation drawn up by Berson. Thus the temperature of maximum sensibility is nearly the same, and the temperature at which the curve begins to slope down most rapidly, namely, 300° C, is the same. The temperature, however, at which the sensibility vanishes is higher the greater the magnetising force,§ the former ranging from 340° C. to 420° C., and the latter from 5 to 18 C.-G.-S. units. The temperature at which the metal loses all trace of susceptibility will probably also vary with the amount of annealing which it has undergone, and certainly varies with the purity, so that the widely different results obtained by different experimenters are not to be wondered at.

The most important point is the one at which the curve begins to slope down most rapidly, and this would appear to be nearly constant for different specimens of fairly pure nickel well annealed. The nickel should, however, be fairly pure, for the writer has in his possession a piece of nickel wire which has its magnetic susceptibility and most other physical properties nearly the same as that of pure nickel, but which, nevertheless, behaves as regards its thermo-magnetic properties like iron. The temperature where the most rapid slope begins is, for both temporary and total magnetisation, about 300° C., and if nickel be employed in the construction of a thermo magnetic motor the most advantageous limits of temperature between which the metal should be allowed to work would be 300°C. and 320°C. The writer has determined, from his own experiments on temporary permeability, the rate at which the number of lines of force would diminish with rise of temperature between the above-mentioned limits in a manner which will be understood from the following table :—

Temperature in deg. C. t.	Magnetising force in C.-G.-S. units. M_f	Temporary magnetic permeability. M_p	Difference between values of M_p at 300° C. and 320° C. divided by $\frac{\Delta M_p}{\Delta t}$.	$\frac{\Delta M_p}{\Delta t} + M_f$
300 320	4·959	141·0 96·6	2·22	11·1
300 320	11·571	95·5 73·8	1·08	12·5
300 320	18·183	84·8 69·1	0·79	14·3

This table furnishes important practical information, as it shows that we work with best advantage with comparatively low magnetising forces; in fact, we see from the fifth column that, with a magnetising force of about 5 C.-G.-S. units, we get for each degree rise of temperature a decrease of 11 lines of force per sq. cm., and with a force of 18 only a decrease of 14 lines.

The loss of magnetic susceptibility in nickel seems to be remarkably sudden in the case of a very thin layer of the metal, as the following experiment will show :—A brass wire 1mm. in diameter was coated with a thin layer of nickel by electrolysis, and a piece of it, about 2cms. in length, was suspended horizontally in a cradle of platinum between the pole-pieces of a powerful electro-magnet in a direction perpendicular to the lines of magnetic force; the platinum cradle was supported by a platinum wire 12 inches long and $\frac{1}{100}$th inch in diameter. The nickel-plated brass wire was heated by a burner to a temperature of about visible red, and the electro-magnet was then excited by five Grove's cells. Not the slightest effect of the intense field seemed to be experienced by the nickel, even after it had been cooling for several seconds. The magnetising circuit was now broken, leaving only the residual magnetism in the pole-pieces, when, after a few seconds of further cooling, and without *the slightest preliminary warning*, the piece set axially with startling suddenness.

The writer has also made experiments on the temperature at which iron begins to lose rapidly its magnetic properties, and from some investigations which he has made on the elasticity and internal molecular friction of iron at high temperatures,* he inferred that iron would begin to lose its magnetic properties at a temperature of about 550° C. The above estimate of temperature was only very rough, and M. Ledeboer's estimate of about 560° C. is probably nearer the mark for annealed iron; but it is evident from the experiments of Faraday and others quoted above, that the temperature of sudden loss of susceptibility will vary somewhat considerably with different specimens of iron and steel.† Whatever this temperature may be, however, there is an indubitably sudden change in the internal friction of iron in the near neighbourhood of it. Here the internal friction is at least six times as great as at a temperature of 20° C. and it goes on rapidly rising until there is another sudden jump somewhere above 1000°C., when the internal friction is more than twenty times as great as at 20° C. At the last critical temperature most extraordinary changes take place in iron; the metal assumes, as it were, a partially fluid condition, and begins very suddenly to yield permanently to the slightest force of extension, torsion, or flexure. Besides this sudden permanent yielding there are other remarkable changes which occur at the same temperature when the iron is under stress or strain,‡ which have impressed the writer with the belief that there are *two* critical temperatures in iron at which the molecular architecture is suddenly changed, one at the point when the metal begins to lose its magnetic properties, the other at a much higher temperature (somewhere about 1000° C.)

The relative susceptibilities of iron and nickel vary so much with the magnetising force that it is difficult to form any exact estimate of the relative effects of the two metals when used for thermo-magnetic motors; but it would seem to follow from the experiments of M. Ledeboer and those of the writer that the decrease in the number of lines of force per centimetre for for increase of 1° C. rise of temperature would not be very different provided the metals were used at those temperatures at which it would be most advantageous to use them. On the other hand, however, since the advantageous mean temperature for iron is more than twice that of nickel, the cooling would be more rapid in the same proportion, and there would be also a much greater range of temperature through which iron might be worked.§ Considered from an economical point of view, there would be no question of the superiority of nickel.

THE SUBMARINE TELEGRAPHS.

The *Central News* learns that the Directors of the Submarine Telegraph Company, having abandoned all hope of obtaining a renewal of their concession from France, have entered into negotiations with the English Government for the sale of their cables and plant. The Government have agreed to purchase at a valuation seven cables belonging to the Company—viz., two between England and Belgium, four between England and France, and one between Jersey and France. The Government will buy, also at a valuation, the ship "Lady Carmichael," the company's buildings in London, Dover, Ramsgate, Beachy Head,

Digitized by Google

and Jersey, with the leases, stores, instruments, and general plant. The Government have also accepted the principle of granting a gratuity to any of the *employés* of the company who, by reason of their age or otherwise, could not be taken into the service of the Post Office. It is further suggested that, instead of handing over the cables to the Government in January, 1889, when the concession expires, the company should continue to work them until the end of the financial year, April 1st, 1889. The directors of the Submarine Company, at the time of entering into the negotiations, made a strong protest against the decision of the Government, and it is understood that, recognising the justice of the complaint, the Government have accepted the principle of granting a bonus as compensation to the shareholders. This, however, is subject to the approval of Parliament. It has been practically decided that on the Post Office taking over the working of the submarine cables, either in January or in April, 1889, a uniform rate of twopence per word shall be charged to France, Belgium, Holland, and Germany.

REVIEWS.

L'Annee Electrique, ou expose annuel des travaux scientifiques, des inventions et des principales applications de l'electricite a l'industrie et aux arts. By PH. DELAHAYE. (Paris: Baudry et Cie.)

This useful annual, which now makes its fourth appearance, is intended to chronicle the progress of the practical applications of electrical science from year to year. The contents are subdivided into twelve chapters, each dealing with a separate branch of the subject. The descriptions of apparatus are well and clearly written; but since the plan of the book does not admit of illustrations or diagrams, the reader will not unfrequently wish to proceed to some more detailed account than is here provided. For this reason we think that M. Delahaye would do well in future issues to give as many references as possible to the technical journals or other publications in which fuller information on any particular subject may be obtained. Since the publication is chiefly of value as a work of reference, we may suggest that it would be as well to facilitate consultation by adding an alphabetical index; at present there is only a table of contents, which, though useful in its way, does not supply the place of an index. Attention to the points which we have named would greatly increase its value, but even as it is the book is one which every electrician who desires to keep abreast of the age would do well to place upon his shelves.

Taschenbuch fur Monteuse elektrischer Beleuchtungsanlagen. (Pocketbook for Electric-Lighting Installations.) By S. VON GAISBERG. (R. Oldenbourg, Munich and Leipsic.)

This is a new and enlarged edition of a little work which originally appeared in 1885. It is intended, as explained in the preface, for the use of foremen in charge of electric-lighting installations, and also for persons having installations carried out in their houses or works, and who being without any technical knowledge of electricity desire to know something of the general principles on which the due efficiency of the installation depends.

The first chapter is devoted to the explanation of electrical terms and the use of simple electrical measuring instruments. The author then goes on to describe briefly the principles of the construction of the different types of dynamos, arc and incandescent lamps, practical measuring instruments, the arrangement of the leads, the management of accumulators, and the electrical transmission of energy. A chapter is also given to the use of dynamos for electroplating. There are many useful hints for carrying out simple repairs and avoiding breakdowns. The different methods of arranging systems of lamps are also very clearly and concisely explained. The author is an engineer himself, and writes in a thoroughly practical style, and readers of considerably higher attainments than those to whom the book is primarily addressed will find many useful hints in its pages. We should certainly like to see something of the same kind, and equally well done, published in English. It would certainly be useful, and we have little doubt that it would have an extensive sale.

Turning Lathes. A Manual for Technical Schools and Apprentices. Edited by JAMES LUKIN, B.A. (E. and F. N. Spon, London.)

The first question that occurred to us on looking at the title-page of this book was, why should the writer describe himself as "editor" of the manual? The reason soon became evident on turning over the pages, as the work is virtually a trade catalogue of a certain firm of tool manufacturers, and the letter-press seems to be written as much to advertise their wares as to instruct the learner. We must, however, congratulate the writer on having succeeded, in spite of the restrictions imposed upon him by the design of the book, in producing a useful, readable and thoroughly practical little manual for the instruction of aspirants to the turner's art. The book is well arranged, and gives a considerable amount of information in a very compact and inexpensive form. The last chapter, which is devoted to the description of a milling machine made by the firm alluded to, appears to us out of place in an elementary manual of this kind, and would hardly, we should think, have been included if the writer had been free to use his own judgment in the matter.

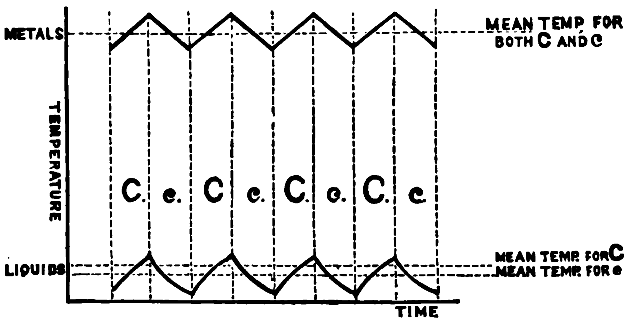
ON OHM'S LAW IN ELECTROLYTES.*

BY G. F. FITZGERALD, F.R.S., AND FRED. TROUTON, TRIN. COLL., DUBLIN.

The result of our experiments up to this is to ascertain that h in $[v = v_0 (1 - h c^2)]$ is certainly less than 5×10^{-6}.

This time last year it was hoped shortly to attain much greater accuracy than had been reached, but it is clearer now than then what a difficulty the "heating effect" is.

This inherent difficulty in studying Ohm's law in liquid electrolytes, as compared with metallic conductors, may best be understood by considering the increased difficulty which would be introduced in the determination for metals if the wire were to be immersed in an electrically non-conducting liquid. When the wire loses heat, chiefly by radiation, as when in air, its general temperature is so much above the temperature of surroundings that its rate of cooling may be considered constant for the small changes of temperature which can occur if the alternations from the larger to the smaller current be sufficiently frequent. The temperature thus rises at a constant rate while the larger current runs, and so falls again during the time the smaller current is on, the average temperature in both cases being the same. The upper part in the diagram illustrates this.



However, with the same frequency in changing currents, the average temperature, while the larger current runs, may be made very different from the average temperature while the smaller current is on, by immersing the wire in liquid, for the general temperature of the wire can then be only slightly above the temperature of its surroundings, so that the rate of cooling can no longer be considered the same throughout. The lower part of the diagram is intended to roughly represent

* Paper read before the British Association Meeting at Manchester, September, 1887.

Digitized by Google

this. The temperature curve is concave to the lower side while the larger current runs, but is convex as the wire falls in temperature during the period of the smaller current. The "temperature effect," if thus introduced, would have to be met by increasing the speed of the contact breaker, or otherwise smaller currents should be used, which, of course, would diminish the refinement in the determination of "*h*" correspondingly.

Now this is similar to the case of a liquid electrolyte, the smaller arm of the bridge rapidly losing heat by convection from its necessary proximity to the larger bodies of liquid at both ends. The actual rise in temperature in one experiment was ascertained, through the increased resistance, to be much less than 10deg., while in some of the determinations made with metals the wire fused during the experiment, so high a temperature was reached.

The greatest speed found necessary for the contact breaker in the determination with metal conductors, when "*h*" was ascertained to be less than 10^{-12}, was about 100 per second. The fastest of the three forks we have successively employed is about 160 per second, but a much faster fork has been prepared, though as yet it has not been got to work satisfactorily.

The diameter of the smaller arm has been reduced considerably since last year. One hole of ·0027 centimetre was bored with a specially prepared needle in extremely thin mica. So that not much more can be done in this direction. The density of the greatest current which could be used through this without "heating effect" was about ten amperes per square centimetre.

DISCUSSION.

Sir WM. THOMSON: I am sure we have all been struck with the main result brought out that when allowance is made for a change of temperature, which he (Prof FitzGerald) has so interestingly explained, the accuracy of Ohm's law is verified by the experiments he has described to the extent of $\frac{1}{2000}$ per cent—a most important result, as you will all see.

Prof. MALLET: I have always been profoundly impressed by the views put forward by Profs. Williamson, Albert and Clausius, and the difficulty suggested by Prof. FitzGerald just now offers an admirable illustration of the great advantage we derive from Sections A and B meeting together. In the suggestion that has been made as to the improbability of Prof. Williamson's view—namely, that the hydrogen atoms would some of them be certain to escape from the surface of the liquid—it appears to me that the distinction which we chemists are called upon to insist—the distinction between the atom and the molecule—has been overlooked. We know nothing at present of hydrogen in the form of single atoms. In order to form a molecule they must escape. The tendency to unite with chlorine atoms appears to be stronger than that of the hydrogen with other hydrogen atoms, and consequently we see a reason why the hydrogen atoms should remain in a state of perfectly immobile equilibrium.

Prof. FITZGERALD: I have already stated that there are hydrogen atoms in the liquid, and I should expect that some of them should unite in the course of one hundred years, and thereby escape from the liquid. The great beauty of the arrangement is that the hydrogen-chlorine will not recombine.

Prof. O. LODGE: The dissociated hydrogen atoms in a liquid are similarly charged, and until they have given up those charges they cannot combine with each other and escape. At the electrodes they do part with those charges, and they then can come out of the liquid, but until they have done so they must remain isolated. At the same time the Clausius hypothesis does not necessitate the idea of atoms moving about freely. All that is necessary is to assume frequent interchange of atoms among the molecules. Unless you accept such interchanges as going on I do not see how chemists are to explain double decomposition and other things. All that is wanted is that each molecule shall not always consist of the same individual atoms, but that interchanges shall always be going on.

ON THE HEATING EFFECTS OF ELECTRIC CURRENTS.*

BY WILLIAM HENRY PREECE, F.R.S.

On March 19, 1884, I submitted to the Royal Society a paper on the heating effects of electric currents,† showing the strength of current necessary to fuse the fine platinum wire employed for protecting submarine cables from the ill effects of atmospheric electricity. The paper proved that the law that regulates the production of heat is one which can be expressed by the formula $C = ad^{3/2}$, "a" being a constant dependent on the metal used, and "d" the diameter of the wire. The current observed was that which heated the wire up to the point of self-luminosity (525deg. C.).

Since "cut-outs" of the same character as the cable lightning protector have become an essential feature of all electric lighting installations, to act as safety fuses when from accident or design an excess of current is allowed to pass through the conductor, it became most desirable to determine the current that would fuse wires of different diameters, and of different materials, so as to determine the coefficient a for all metals. The best material to use and the proper dimensions of the fusible wire to be employed for the protection of the electric light conductors would thus be easily deduced.

My source of electricity was a large secondary battery of 52 cells. I could regulate the current flowing at will by a rheostat of thick iron wire, and by varying the number of cells. The current strength was calculated by measuring the potential difference at the ends of a thick flat platinoid bar, whose resistance was 0·1822ω, inserted in the circuit, and so large that it would not perceptibly warm up nor have its resistance appreciably increased with any current used. The sizes of wire experimented upon were limited by the current. It is not safe to draw upon secondary cells for more than 10 amperes per negative plate of the dimensions at present followed. The packed plates disintegrate and become damaged with too great an output of current. Hence all my experiments were made with currents well within the range of the battery. I obtained samples of wire of various metals and of various diameters from 0·004in. up to 0·040in. It is convenient to take these measurements in thousandths of an inch (*mils*), for all our manufacturers and electric light engineers in the United States and the United Kingdom work to this gauge. The conversion of the values thus obtained into the metrical and more scientific system is very simple. The wire to be experimented upon was clamped between two small brass binding screws fixed upon a dry wooden stand.

I pointed out in my previous paper how the cooling effects of the terminals or binding screws might vitiate the results, and how necessary it was to experiment on wires of sufficient length to prevent any error occuring from this cause. I used lengths of 6 inches to determine the constants for wires free from the cooling effect, but lengths of 1¼ inch with massive terminals to determine the constants for wires used in practice as "cut-outs."

The cooling effect of the terminals very seriously affects the efficiency of the cut-outs used in actual practice, and the larger the fusing wire and the terminals the more serious is the error introduced. On the other hand, the greater the lengths of wire used as a fuse the greater the resistance inserted, and the efficiency of the system itself may be reduced. Cut-outs, therefore, should be employed sparingly and with judgment, and the fusing wire should not be so short as to impair the fusing point.

In the following tables I have tabulated the results of the numerous experiments made.

When we consider the irregularities in drawing these fine wires to true cylinders, the difficulty in determining the current at the exact moment of fusion, and the variation in the specific resistance of the metals, I think the results must be considered very satisfactory in support of the law.

Three points of observation were taken:—

1. The melting point of a small flake of shellac placed on the wire, which may be taken at 77deg. C.

2. The point of self-luminosity, 525deg. C. This was only determined roughly in air without the dark chamber I employed previously.

3. The fusing current.

NOTE.—The wire becomes red, and then immediately much brighter (a dull white), owing probably to oxidation. To reproduce faint redness without breaking the circuit, the current can be considerably reduced. "a" is the current which caused the first visible rays of light, and so quickly changed the wire to a brighter state of incandescence, while "b" is the reduced current which reproduced the first redness. If the experiment be repeated the same effects are obtained, although the molecular structure of the wire seems to be much changed by the first heating. After fusing the wire a white powder, alumina, is found, and sometimes a white opaque bead. A wire 18 mils diameter and 10 inches long was raised to faint red with 11·22 amperes; it glowed (dull white) on one side of loop with 11·58 amperes, and when the heat had apparently spread over the whole length uniformly redness reappeared, and the current was found to be again 11·22 amperes. The wire was next raised to a moderately white incandescent state with 15·93 amperes, and with this current broke in two minutes.

(To be continued.)

Electrical Meteorology.—Advices from America state that four experimental weather stations have been established with the view of ascertaining, if possible, the laws governing atmospheric electricity and comparing the laws with the variations of the barometer. The stations have been distributed as follows:—One at Washington, the second at the Rose Polytechnic School, Terre Haute, Indiana, a third at Boston Institute of Technology, and the fourth at Cornell University, Ithaca, New York. It is thought that observations of atmospheric electricity will afford much more reliable data for predicting storms than those in present use. The potential, it is said, fluctuates before the storm in a manner exactly analogous to the barometer. At the Cornell station variations were recently noticed two days before the storm occurred.

NOTES FROM SCANDINAVIA.

(FROM OUR STOCKHOLM CORRESPONDENT.)

An electric installation of considerable interest will soon be effected at Porsgrund, Norway, the corporation of that town having just purchased the Porssiäs Works with its water power, with the intention of using the latter for electric light and for transmission of the power, by electricity, to various industrial establishments in the town. The waterfalls and the works belonged to a bankrupt estate, and there had been several auctions before the corporation thought of acquiring the property. The price was only about 120,000kr., and there can be no doubt that the waterfall will afford a decidedly cheaper power than could be obtained by coals. A mill is attached to the property, the rental of which will probably be enough to pay interest, &c., so that the power for electric purposes will hardly cost anything. It is calculated at 1,619,000 hours. The waterfall, with lowest water, has a capacity of 300 horse-power. For the electric light streets, shops, manufactories, and private residences are reckoned to require 150 horse-power (for 1,200 lamps) and the Porssiäs Mill only requires 60 horse-power. The distance between the waterfall and the town is only 800 metres, so there will be no difficulty about the transmission.

The charge for inland telegrams in Norway has from the beginning of the present year been reduced to 50 ore (6½d.) for ten words, and this reduction has already brought about a very considerable increase in the number of messages sent.

As a proof of the general use into which the telephone has come in Sweden, I may mention that the Skåne telephone system, which comprises several smaller towns, had 1,306 subscribers at the beginning of the present year. Malmö had 560 subscribers, Helsingborg 136, Lund 125, &c. There are altogether 21 central stations.

In Sweden the Government has proposed a yearly tax of 10kr. on each telephone which has connection with a central telephone station. The reason assigned by the Chancellor of the Exchequer is the serious loss caused to the State telegraphs by the ever-increasing number of private telephones.

A central electric station is under contemplation in the town of Sundsoall, Sweden; it is intended for 1,000 incandescent lamps, although it may be started with a considerably smaller number.

The Swedish Government has during the year 1887 erected 386 new telephone stations.

The first step towards lighting streets in Malmö, Sweden, by electricity has just been taken, two arc lamps of 500 candle-power each having been placed in the vicinity and at the expense of the Hotel Kramer.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *Feb. 4th*, 1888.

New York City is all agog with big schemes for improved rapid transit. As many of your readers are probably aware, New York City is an island closely resembling a forked tongue. The population has, until the last few years, been concentrated at the tip of the tongue, where it runs out seaward between the waters of the East River and the Hudson River. For a long time, for lack of convenience of travel and because of the high rates, the overflow of population found its way generally into Brooklyn and the countless scattering villages of New Jersey. A few years ago the rapid transit facilities of the island were increased by the extension of the elevated railroad system from one end of the island to the other and into the adjoining country, so that no change of cars was necessary, even in a journey of from 8 to 10 miles; but now again, owing to the rapid growth of the city, accommodation is once more seriously inadequate, and various grandiose schemes are daily brought to notice for meeting the necessities of the situation and reaping the reward. My reason for mentioning these facts is that Mayor Hewitt has himself now taken the matter in hand, and has, through the medium of a message to the Board of Aldermen, submitted to the public a comprehensive system of rapid transit, such as is likely to meet both the present and future needs of the city. I need not enter into the details of the scheme, as they could not be understood without a map, and even then would probably lack clearness, but I want to emphasise the fact that in this really remarkable message electricity plays a most important part. I am not aware that it has ever before been so prominent in an official document of the kind. In several places Mr. Hewitt proposes that the cars to be employed shall be operated by storage batteries or by electric power in any shape that may be deemed satisfactory. In one part, dealing with the question of tunnels, he alludes to the rapid improvement of the electric motor rendering it valuable for such service, and says: "I have no doubt myself that the steam engine will pass out of use in cities in a very few years." An utterance like this from such a man as Mr. Hewitt, who is not only statesmanlike in his views and training but well versed in engineering matters, is of the highest significance. Mr. Hewitt also adds: "Between open cuts and tunnels there will only be a change from daylight to electric light, which happily is now so perfected that what would ten years since have been an insuperable objection to the use of tunnels is altogether removed." It is perhaps worthy of note that over a portion of the route to which this notable message refers from City Hall to the Grand Central depot, a Julien car is now in regular operation, and that by a contract with Mr. Vanderbilt it is to be supplemented by ten more as soon as they can be built.

There has been of late in this country quite a pronounced movement looking to the general introduction of anti or non-magnetic watches. On several of the western railroads orders have been put in force compelling each conductor and locomotive engineer to carry an accurate time piece, and to submit it for inspection regularly; and the big Erie Railway Company has now taken the same action. There has been quite a run on shield devices, and a large sale has also been enjoyed by a non-magnetic watch of Swiss manufacture. The well-known Waltham Watch Company have now given their attention to the subject, and have just put on the market the first non-magnetic watch made in this country. They state as their reason for doing this that so many watches were brought to them to be demagnetised that they thought it well to provide prevention rather than cure, and they say that the balance, hair spring, and escapement are made of a non-magnetic composition, arrived at after a long series of experiments. It is a peculiar fact that the cheap Waterbury watch, whose chief use here has been to supplement the charms of shoddy clothing and swell the subscription list of cheap newspapers, has been about as successful a "non magnetic" as any yet introduced.

There is no small amount of grumbling in our large cities as to the time consumed in the delivery of local messages. Where district messengers are used delay can be accounted for, but it has been difficult to see why a telegram sent between two points only a few miles apart should require pretty well an hour for its delivery. It is here that the telephone proves itself so formidable a competitor, for even at its worst, it will put a message through in about five minutes. How to improve this local delivery might well occupy the attention of inventors and managers not only here, but in England, where, I am told, the same trouble is experienced. Perhaps the electro-pneumatic despatch system may help us out. The discussion here over the propriety of Government telegraphs has brought out some interesting information as to the methods in vogue of sending news before the telegraph became practicable. Thus it appears that at the opening of the Erie Canal in 1825 the news was communicated from Albany to New York and back again in fifty-eight minutes. This is quicker than a telegraph message could be sent and answered under ordinary telegraphic conditions to-day, and hence we have some sapient newspaper comments. The fact is lost sight of, however, that no message was actually conveyed, but that a signal was agreed upon, and that it was nothing more or less than the firing of a cannon. The guns were placed within hearing distance of each other all

Digitized by Google

the way between the two cities, and as the preconcerted signal had its meaning for everybody, there was not much likelihood of "bulling" the message. If any of my newspaper friends want to go back to that ancient system they can, but I hope they will not expect me to live near the line when it is set up.

I mentioned not long ago a revival of schemes for utilising Niagara. One of these has now been proposed by the Niagara Falls Hydraulic Motor and Power Company of this city, which has as its secretary Mr. George S. Bowen, with whom the idea of the National Electric Light Association originated. The plan of the company is a little startling. It is proposed that shore abutments of granite shall be erected on each side of the Niagara River just above the Falls. Between these abutments will stretch a steel cable 10in. in diameter. Dependent from the cable, and swinging freely at the very lip of the Fall, will be large float boats made of steel, and loaded with ballast. They will be moored nose up stream, and at the stern will be large wheels connected together by a universal coupling shaft, so as to allow the current or the ice to move the boats without interfering with the revolution of the wheels. This shaft is to be connected with an immense power house on the American shore, in which are to be placed a large number of dynamos, grinding out current for Buffalo, Rochester, or any other city within presumably convenient distance. This is a very pretty scheme, and all that is necessary for its successful execution is that Jules Verne should be invited to act as engineer of the works. The position of the men employed on these pontoons, rocked on the bosom of the deep and shrouded in perpetual mist, will be a peculiarly interesting one. It is probable that when Sir William Thomson proposed the utilisation of Niagara for distributing electricity he was not aware of the fertility of invention that would be brought to bear on the task.

The Government telegraph discussion drags along, and there is as yet no intimation that this Session of Congress will witness any decisive action on the subject. A Bill has now been introduced into the United States Senate to subject telegraphy to the jurisdiction of the Inter-State Commerce Commission, in the same way as the railroads now are. It will be the business of the commission to prevent any objectionable agreements or combinations; to interfere when any unfair preference or advantage is given to any person, and to remove the grievances of injured parties. The Bill declares it unlawful for any telegraph company, directly or indirectly, to make discriminating rebates, drawbacks, or the like.

The New York Electric Club opened its house in East Twenty-second-street this week. There was a large attendance, and Prof. H. A. Rowland read an interesting address. The house has a complete electrical equipment, and contains a number of electrical novelties and toys. The building does not belong to the club, but is rented, and the money for furnishing, decorations, &c., has been raised by bonds. The membership consists chiefly of business men, and comprises some of the most jovial spirits in town. In catering to the social element, the club has a well-defined mission, which it now bids fair to discharge. Many experiments have already been made to demonstrate the conversion of electrical energy into mechanical energy, and this is now usually demonstrated by the conversion of magneto-electric into electro-magnetic action, or the re-conversion of current into power by means of the motor. In a lecture before the Cornell University Prof. Nichols demonstrates in a very brilliant experiment the reversibility of the static machine into a motor. He accomplishes this by the simple method of generating a continuous static charge by one machine as a generator, and leading the charge to a second one which starts off at once and runs as a motor. It would be interesting to know what the efficiency of this combination is, and what the loss through "leakage" is.

A writer in a recent article, just printed here by one of the electrical papers, in calling attention to the old scheme of employing windmills for the purpose of driving dynamos and charging storage batteries, claims that if the true economy and efficiency of the windmills, as constructed to-day, were more generally known, we should see a large number of these motors used for the purpose mentioned. He shows that the modern windmill is constructed to keep constant speed with varying velocity of wind, and that at least in this country there is sufficient wind—eight hours out of the twenty-four all the year round—to keep the windmills going. There is more in this, I think, than would at first sight appear, and with the improvements that are constantly being made in storage batteries, it does not seem unlikely that we shall in the near future see the utilisation of a power now much neglected. Why could not Sir David Salomons look into the subject and make some more of his practical tests ?

CORRESPONDENCE.

THE COEFFICIENT OF SELF-INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: If your correspondent "G. B." will refer to Cumming's "Electricity," p. 207, 1st edition, he will see that the author there defines the coefficient of self-induction of a circuit to be numerically equal to *half the number* of lines of force embraced by the circuit when removed from all other circuits and carrying unit current. Also, if there are two circuits carrying currents i_1 and i_2, and having coefficients of self and mutual induction respectively L, N, and M, he gives as the value of the total electro-magnetic energy

$$L i_1^2 + M i_1 i_2 + N i_2^2.$$

It is better to define the coefficient of self-induction, as does Maxwell, as numerically equal to the *total number* of lines of force embraced by the circuit when removed from other circuits and carrying unit current, and this definition renders the expression for the total energy in the case of the two circuits,

$$\tfrac{1}{2} L i_1^2 + M i_1 i_2 + \tfrac{1}{2} N i_2^2,$$

which is mathematically homogeneous. The matter, in one word, is this: Cumming takes as a value for the unit of self-induction of a non-magnetic circuit a quantity which is twice as great as that which I, following Maxwell, have done; hence our L's are not the same. Further discussion of this point will be found in notes to follow.—Yours, &c.,

J. A. FLEMING.

BATTERY CARBONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to your correspondent "Carbo," I may say that I am aware there is a wide-spread (though, in my opinion, erroneous) idea that no compressed carbon can be made to equal cut or retort carbons. Now, the essential conditions of good battery carbons are the following:—

(1) That they should not disintegrate.
(2) That they should be dense.
(3) That they should be uniform and of high conductivity.
(4) That they should contain little or no mineral impurities.

From experiments made by ourselves and our customers, extending over a period of more than three years, we have ascertained beyond doubt that the compressed plates manufactured by this company are *less* liable to disintegration than cut plates, and are of a higher conductivity than these. They are also more dense and uniform, and contain much less mineral matter.

We are so convinced of their superiority in all these respects that we should be quite prepared to run them against any cut plates.—Yours, &c., HENRY LIEPMANN.

Millwall, E., 15th Feb., 1888.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In answer to your correspondent "Carbo's" inquiry in your last week's issue I have had considerable experience

Digitized by Google

with carbon plates, both for battery purposes and for use as insoluble anodes. In decomposition cells my experience has been decidedly in favour of the retort carbon in strong acid solutions. I have some that were sawn from the blocks that have been in use constantly for four years and are quite as good now as at first. The compressed carbon I find does disintegrate, especially when used as an anode. If your correspondent has the convenience to grind the retort carbons and burn them, I shall be glad to tell him the method I have employed to manufacture a carbon screw, 5ft. in length and 1ft. diameter. It is a very troublesome process, requiring a number of burnings and very good moulds, but I have had a screw in use for a year that does not show signs of disruption, although a very heavy current is passing.—Yours, &c., G. J. Atkins.

1, Pembury-avenue, Tottenham, London, N.,
February 15, 1888.

ARC LIGHT CARBONS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The subject of cheap carbons having been often discussed in your columns, may I be allowed to draw the attention of those interested in the subject to the excellent lighting of the Victoria Station (L. B. and S. C. Railway) on the Wood's system, and to state that the uncoppered 11 mm. carbons there used are of English make?—Yours, &c.,

Chas. F. Cathcart,
Manager Globe Electrical and Engineering Co.
7, Carteret-street, Westminster, S.W.,
February 14th, 1888.

[We regret that the etiquette of technical journalism compels us to omit the latter portion of our correspondent's communication, in which he enters into particulars as regards cost and terms of delivery, &c. We have no objection to add, however, that the price is lower than we have yet known to be quoted for really good carbons.—Ed. *E.*]

PHYSICAL SOCIETY.

ANNUAL GENERAL MEETING.

The annual general meeting of this society was held at South Kensington on Saturday, Feb. 11, Dr. J. H. Gladstone, F.R.S. (vice-president), in the chair.

The Chairman read the report of the council for the past year, and expressed regret at the losses the society had sustained by the deaths of Dr. Stewart (their late president), Prof. Kirchhoff, Mr. Coutts Trotter, and Prof. Humpidge.

The council regret that no increase of members has taken place during the past year, and hope that the advantages offered by the society may be more fully appreciated in future. Obituary notices of Dr. B. Stewart, Mr. Coutts Trotter, and Prof. Humpidge were then read. The treasurer's report shows that the financial condition of the society is very satisfactory. On the motion of Mr. Lant Carpenter, seconded by Mr. Inwards, the reports were adopted. The following gentlemen were elected members of council for the present year :—President, Prof. A. W. Reinold, F.R.S.; vice-presidents, Dr. E. Atkinson, Prof. W. E. Ayrton, F.R.S., Shelford Bidwell, F.R.S., and Prof. H. M'Leod, F.R.S.; secretaries, Mr. Walter Bailey, M.A., and Prof. J. Perry, F.R.S.; treasurer, Prof. A.W. Rücker, F.R.S.; demonstrator and librarian, Mr. C. V. Boys; other members of council, Hon. R. Abercromby, R. H. M. Bosanquet, M.A., W. H. Coffin, Conrad W. Cooke, Prof. F. Fuller, M.A., W. N. Shaw, M.A., A. Stroh, Prof S. P. Thompson, D.Sc., H. Tomlinson, B.A., and G. M. Whipple, B.Sc. On taking the chair the new President expressed his sincere thanks for the great honour the society had confered upon him. Prof. Fuller proposed a vote of thanks to the Lords of Committee of Council on Education for the use of the rooms and apparatus of the Normal School of Science, which was seconded by Mr. Shaw, and passed unanimously. A cordial vote of thanks to the council and officers of the past year, moved by Dr. Blaikley and seconded by Prof. Ramsay, was duly acknowledged by the President.

A paper was then read by Mr. T. Pelham Dale "On the Limit of Refraction in Relation to Temperature and Chemical Composition." A point of interest to electricians in this paper is the anomalous dispersion of light found to exist in selenium, in relation to the influence of light on its electrical properties.

Mr. Bosanquet then read a paper entitled

Note on the use of the Term "Resistance" in the Description of Physical Phenomena.

The author stated that his paper owed its origin to a quotation at the previous meeting of the society by Prof. S. P. Thompson of a remark of Dr. Hopkinson's, objecting to the use of the term "magnetic resistance." The author defines his use of the term "resistance" with regard to physical phenomena in general as follows:—

Any physical change may be considered as made up of two component parts, namely, a cause and an effect. When there is an opposition to the change of such a nature that it is greater the greater the measure of the cause and the less the measure of the effect, such opposition may be defined as a "resistance."

Take, for example, Ohm's law, where we have

$$R = \frac{E}{C} = \frac{\text{Cause}}{\text{Effect}}.$$

Objections have been made to the use of "magnetic resistance" on the ground that it is not of the same dimensions as electrical resistance, and that it varies with different conditions. The same objections, however, may be raised to the use of the term magnetic potential as the analogue of electrical potential, or of magneto-motive force as the analogue of electromotive force. The objection in either case implies that an analogy cannot exist without identity, and therefore falls to the ground.

As another general illustration of his use of the term resistance, the author takes the resistance to compression of a substance, where we have—

$$R = \frac{\text{Pressure}}{\text{Resulting Compression}} = \frac{\text{Cause}}{\text{Effect}},$$

and in this case the resistance is a function of the compression produced just as the magnetic resistance is a function of the magnetic induction. Where the resistance varies from point to point of a curve the author defines the resistance at a point of the curve as the quotient of the small change in the cause by the corresponding small change in the effect, supposing the sum total of the conditions to undergo only a small change in the interval, or, in mathematical language,

$$\text{Resistance at a point} = \frac{d\cdot\text{cause}}{d\cdot\text{effect}}.$$

As an example of this he gives Lamont's formula for a magnet.

The author defends his definition of magnetic resistance as the quotient of magneto-motive force by magnetic induction (a magnetic flux per unit of area), against M. Hospitalier's criticisms that it should be the quotient of magneto-motive force by the total magnetic flux through the circuit, on the ground that his definition, by making the magnetic resistance a linear quantity, greatly simplifies its use for practical calculations.

Prof. S. P. Thompson remarked that he always liked to introduce the terms magneto-motive force and thermo-motive force, in teaching his classes, as the analogues of electromotive force, as he found it a great help in impressing on their minds that electromotive force is not a force, and must not be confounded with it. He mentioned that Rankine used the term thermal resistance for the reciprocal of conductivity, and we may write

$$\text{Thermal resistance} = \frac{\text{Thermo-motive Force}}{\text{Resulting Flux of Heat}}.$$

He stated that he usually gave Boyle's law to his students in the form

$$\frac{\text{Pressure}}{\text{Density}} = \text{Constant},$$

instead of in the form,

$$\text{Pressure} \times \text{Volume} = \text{Constant}.$$

Alluding to the characteristic curve of a series dynamo, where if amperes be taken as abscissæ and volts as ordinates, the machine being run at constant speed, the resistance at any point of the curve is given by the tangent of the slope at that point, Prof. Thompson suggested that it would be very useful, both for dynamos and electromotors, to draw characteristic curves expressing the mechanical conditions.

For example, in a dynamo we might take a constant driving moment instead of a constant speed, and in an electromotor we might take either a constant potential difference or a constant current. For a shunt-wound motor we might take the speed for abscissæ and the torque on the axle for ordinate, when we should have

$$\text{Resistance to driving} = \frac{\text{Torque}}{\text{Speed}}.$$

Prof. Ayrton agreed with Mr. Bosanquet's expression

$$\text{Resistance} = \frac{\text{Cause}}{\text{Effect}}$$

Digitized by Google

provided this ratio were fairly constant within the limits considered, as is the case with magnetic resistance except for very small magnetising forces and near saturation, and did not agree with Dr. Hopkinson in rejecting the term because there were bends in the curve.

Similarly he would not reject the term electrical resistance if it should be found, as he expected, that for a sheet of metal with a large current passing through it, the ratio E/C for a given temperature varies with the strength of the current. He did not think, however, that the term "resistance" ought to be used if there were great variation. For example, he considered that we should never have used the term "electrical resistance of a conductor" if R had varied as C, say, or as C^2.

Prof. FOSTER mentioned that in teaching mechanics to his students he had found it convenient to define inertia as the measure of resistance to change of velocity, its value being given by

$$\text{Inertia} = \frac{\text{Force}}{\text{Accleration}}.$$

Moment of inertia he defined similarly as the measure of resistance to change of angular velocity.

PHYSICAL SOCIETY OF GLASGOW UNIVERSITY.

An ordinary meeting of this society was held on Friday night, the 10th inst., Mr. Maclean (president) in the chair. Mr. Thomas Gray, B.Sc., exhibited and described an improved apparatus for the determination of the intensity of the horizontal component of the earth's magnetic field.

In this apparatus a magnetometer, consisting of a small magnetic needle about 1 cm. in length, mounted in a light aluminium frame, carrying a small mirror suspended in a vertical glass tube fixed to a wooden base plate, is supported on a light but rigid wooden frame, which is capable of turning round a vertical axis. Two deflector magnets, mounted on suitable stands, are carried by a strip of thick glass, which turns round the same vertical axis in such a way that the deflectors are always on opposite sides and at equal distances from the magnetometer needle. The method is in principle the same as that of Gauss, and the apparatus is a more perfect form of that described by Mr. Gray in the *Phil. Mag.* for Dec., 1885, the *sine* method being adopted in this case, instead of the *tangent* method, as described in the paper just referred to.

TECHNICAL EDUCATION.

A conference on Technical Education was held on Wednesday evening, at the Victoria Music Hall, South London, Captain Sir Douglas Galton, K.C.B., in the chair.

The CHAIRMAN announced that letters expressing regret at inability to attend had been received from Prof. Foxley, Prof. Seely and several other gentlemen. Prof. Roscoe, that great promoter of technical education, wrote:—"Such conferences as these are of the greatest value for enabling an understanding to be arrived at between employers and workmen of what is really required for the furtherance of technical education. Our National Association has done and will do much in this direction throughout the country, but it is of the greatest importance that here in London the subject should be discussed, and the issues well considered and thought out."

After a lucid address on the general subject by the CHAIRMAN,

Dr. FLEMING advocated a great scheme of national secondary and technical education under the management of Government, and detailed the methods which such an organisation should adopt. He moved: "That it is desirable to deal in the present Session, by introducing a Bill, with the question of national education, and that a constituent element be the establishment of a Minister of Education presiding over a National Council of Education."

Prof. JOHN PERRY, in seconding the resolution, said he might to some extent be regarded as a little antagonistic to some of the views usually brought forward before meetings of this kind by professional speakers. True, he was a professor, and a Fellow of the Royal Society, but as a matter of fact he had been apprenticed as a workman, and worked at the bench (cheers). He had the most intense sympathy with workmen. On the whole, the workman is fairly right in many of his notions; in bringing them forward he is a little inarticulate; he says nonsense very often; he speaks rubbish; but there is a great deal of meaning underlying that rubbish, and it is the duty of those who deal with the legislation of this country to find out the grains of wheat among the mass of chaff. He perfectly agreed with what had been said by the Chairman and by Dr. Fleming as to the advantages of machinery. Of course we could not destroy machinery. Without isolating ourselves completely, and reducing England to the position in which Japan was 25 years ago, we could not destroy machinery. What we call bad trade is after all simply that our machinery is not as perfect and our methods of working are not as perfect as they ought to be, and that we had to improve them. There is more skilled labour on the whole employed now than there was twenty-five years ago or fifty years ago. For every weaver like Silas Marner of one hundred years ago weaving in the neighbourhood of a village, the weaver of the village—for every one man like that there are one hundred men now employed at over £2 a week, and perhaps a thousand women and boys. All this was quite true, and it was folly to deny the advantages of machinery. But there was one thing which did not seem yet to have come home to our legislators, and that was that machinery was creating a wonderful amount of unskilled labour in this country. Nowadays a boy at the wages of 15s. or 18s. a week by simply turning two or three handles could turn out work which not long ago would have required two weeks' labour, and not turned out the work so well. But what was the future of the boy? It was quite true that with machinery a great deal more skilled labour was employed than hitherto, but, on the other hand, there was an immense amount of unskilled labour, and that constituted the great difficulty of the problem that had to be dealt with. Machinery was gradually getting to be the master instead of the slave of men. The remedy for this was technical education. As to the suggestion that there should be technical instruction given in Board schools, he considered that it would be simply iniquitous to do so; it was only increasing the amount of unskilled labour in the country. If a boy were intended to become a practical cabinet maker, or a good fitter or pattern maker, he should not be allowed to touch a tool, especially in such a place as a school workshop, until he was at least 13 or 14 years old. As Science Master at Clifton College he introduced in 1870 the first school workshop, and it had been a great success; but the boys attending that school were not intended to be workmen, and they enjoyed the workshop because it was an agreeable variation from cricket and football and other amusements. The English technical education problem was quite different to that which had been solved elsewhere. The problem of middle class education had already been solved here. In 1880 he published a paper in *The Electrician*, detailing a scheme of technical education for the middle classes, and that scheme had since been successfully worked out at the Finsbury Technical College. The middle class technical education was merely the fringe of this question. As to evening classes meeting the difficulty, he had lectured to evening classes, and he felt that the working men who attended them were simply heroes. One of his pupils at the present time did not get home after attending the classes till midnight, and had to get up at four o'clock in the morning. Of course if that young fellow lived he would be a very successful man; but was it possible to compel the working men of this country to attend classes in that fashion? He would like to see a revival of the old apprenticeship system (he belived it survived only at Sheffield) by which the workmen themselves were allowed to take lads as apprentices. It was no use trying to accomplish technical education by means of night classes; the master should give a third of the working day to the practical teaching of his trade and of the principles underlying the trade. Already there were half-time classes for children in towns where there were mills; why should not there be third-time classes, where apprentices could devote a portion of the working day to obtaining the technical instruction which was absolutely essential? This was the system of technical education for the working classes which he advocated. There might be difficulties in the way; of course there were; but it was for the Legislature to find out the means of getting over those difficulties. It was for Parliament to compel the masters and employers to carry out some such a scheme. Until something of the kind was done, it would be found that the unskilled labour in the country would increase; it was already reaching tremendous proportions, and, unless steps were speedily taken to diminish it, the people would soon become the mere slaves of machinery, instead of reaping advantages from it.

A letter was read from Prof. Lant Carpenter, in which he complained of the present system of education in the Board schools as being altogether too "bookish." The age at which boys should be kept at day schools should be later than at present, and after leaving day schools they should be compelled to attend evening continuation schools, as was the case in almost every Continental country. Any legislation on this matter would not be satisfactory which simply dealt with the technical education of a select few. The present system of elementary education must be altered so as to make it a satisfactory preparation for technical education.

An interesting discussion followed, and finally the resolution was carried unanimously.

THE ELECTRIC LIGHT AT THE FORTHCOMING GRAND EXHIBITION AT COPENHAGEN.

Our Copenhagen correspondent writes:—

The works in connection with the Grand Scandinavian and International Exhibition, which is to be held this year at Copenhagen, are already far advanced, and the committee are determined that everything shall be ready and in its place on the opening day, May 18th. The main building, a most unique and imposing structure, has already been roofed for several months, and a number of auxiliary buildings, among which is a huge machinery hall, are approaching completion. The electric light will be used in several of the buildings—although not the principal one—and in the splendid grounds which adjoin, and have been amalgamated with the exhibition. Among the buildings which will be thus lighted are the fishery exhibition and the aquariums, the horticultural exhibition, the exhibitions of the army and the navy, the part of the machinery hall containing steam engines and dynamos, &c. The following firms will join in the

Digitized by Google

arrangements for electric light, the first three being Scandinavian concerns :—P. Jürgensen's Electric Company (Limited), Copenhagen ; S. C. Hanberg's engineering and electrical works, Copenhagen ; and Palmerantz and Co., Stockholm. Of foreigners, there are S. Schuckert, Nürnberg, through his agent, Mr. L. Lund, Copenhagen; Siemens and Halske, Berlin, through their agents in Copenhagen, Otzen and Thorsteusen ; and finally the Allgemeine Electricitätsgesellschaft, in Berlin. English, French, and American firms appear to be conspicuous by their absence, although at least one American firm does a very fair business in Sweden.

THE NAVAL TRAINING SHIPS AT DARTMOUTH AND THE ELECTRIC LIGHT.

The Royal naval cadets' training ships at Dartmouth (H.M.S.'s "Britannia" and "Hindostan") are being fitted with the electric light (says the *Western Daily Mercury*) on the supposition that the ships will remain in their present situation for twenty years to come. The installation will consist of about 450 16 candle-power Edison and Swan glow lamps, which will be distributed throughout the two ships. The study rooms take about 60 lamps in the "Britannia" and 50 in the "Hindostan," in several instances portable table lamps being provided. The latter are for the use of cadets when engaged in drawing, &c. The cadets' mess room will be brilliantly lit with 32 lamps of very large size. Each light may be turned on or off at will by means of an independent switch fitted to the lamp. The fittings are of gun metal, and of the pattern generally in use in the Royal navy. The wiring is divided into six main circuits, viz., three pair for each vessel, while all the main cables and branch wires are of the lead covered type, and were specially manufactured for these ships. The dynamo, which is of the Siemens HB type, is designed to give an output of 32,000 watts at a terminal pressure of 82 volts, and will be coupled direct to one of Willan's G size central valve engines, run at a speed of 400 revolutions per minute. The boiler, which will be of the locomotive type, 30 horse-power, will be made entirely of steel, with wrought-iron ashpan and support. It will be constructed to work at a pressure of 120 pounds, and will be fixed on the upper deck of the "Hindostan," where a special house, with corrugated iron roof, will be erected for the electrical machinery. In the dynamo room, one of Scott's patent Admiralty switchboards will be fixed, so that the whole of the circuits can easily be controlled by the attendant. The contractor for the work (with the exception of supplying and fixing the boiler and engine-house, which has been entrusted to Messrs. Hornby and Sons, of Grantham), is Mr. Ronald A. Scott, of London, brother of Commander Percy Scott, R.N., the work being carried on under the supervision of Mr. C. N. Russell, electrician to the contracting firm. Mr. Russell has had considerable experience in this branch of electricity, having superintended the electric lighting of H.M. ships Devastation, Mersey, Severn, and Hero, and of the ships Laurence and Dalhousie. The fitting of the lamps, &c., will be completed in a few weeks, but the boiler, engine-house, &c., will not be ready until nearly Midsummer. The whole work, it is estimated, will cost about £3,000.

ELECTRIC LIGHT IN A DUNDEE CARPET FACTORY.

An important installation of the electric light was inaugurated in Dundee on Saturday last, when the new Lawside Carpet Factory of Messrs. James Paterson and Co. was formally opened. For some years the jute industry has been so depressed that Dundee manufacturers have naturally been unwilling to incur the capital outlay which an introduction of the electric light on a large scale necessitates, and only small installations have been made in cases where, from the works being run at night, electricity is distinctly cheaper than gas. So far as the lighting of an entire factory is concerned, Messrs. Paterson's is the pioneer installation of the district. The factory is entirely new, and is in every way a model one. The whole building, with the exception of stores and offices, is on one floor, covering an immense area, and lighted from the roof. All the shafting is concealed in brick-built tunnels underground, so that there is nothing to interrupt the view overhead, and a perfectly clear space is left for the forest of electric pendants which hang over the warping mills, the looms, and the other machines. The whole building is lighted by electricity. In the offices gas fittings are also used ; but in the main work rooms the only provision for gas lighting is a few Bower lamps to supply light while the people are dispersing after the engine has stopped. These are kept burning low, and are ready to be turned up at a moment's notice.

The dynamo is a compound-wound 100-volt "Manchester" machine by Mather and Platt, with a capacity of 550 16-candle lights. It is driven from the main engine—a vertical tandem Carliss, for which the makers, Messrs. Douglas and Grant, of Kirkcaldy, received a gold medal at the Edinburgh Exhibition. The dynamo room is close to the engine room, near the centre of the factory, and from the main switch-board in it five main circuits radiate to supply different sections of the building. The largest is the weaving shed circuit, in which there are 288 lamps on one switch, fed by a pair of 19—11 mains. These extend along the centre of the weaving shed, a room 260ft. long and 132ft. wide, and branches proceed to right and left over each row of looms. Another large circuit is that of the finishing department, a room 150ft. long and 90ft. wide. Another circuit supplies fifty-two lamps in the offices, and leads to a local eight-way switch-board there by which the separate office rooms are controlled. Another circuit supplies the engine room, and the fifth leads by an underground cable to a group of outbuildings devoted to hand loom weaving. The most distant lamps are 350ft. from the dynamo. Nearly all the lamps are hung from the roof by twin flexible conductors with the usual india rubber and braided silk insulation. The lamps are held in bayonet-jointed vitrite sockets with conical reflectors of white enamelled sheet iron. At the warping mills, and some other machines, and in the office, rising and falling pendants are employed ; over the looms the lamps are hung at a fixed height of 42in. above the cloth. The narrowest looms have one lamp each ; wide ones have two, and some specially wide ones have three. The mains and branches are carried at the level of the beams of the roof. They are all enclosed in wooden casings, and where the casing extends from frame to frame of the roof, as it does in the branches, it is made strong enough not only to span the gaps without sagging, but to stand having a ladder set against it, and even to carry the weight of a man. Hedges and Cockburn cut-outs are used for the mains and branches, and in the offices the rising and falling pendants are each protected by an individual cut-out in the ceiling ferule ; otherwise cut-outs are sparingly used, and only to cover considerable groups of lamps. The electric fittings of the offices are kept distinct from the gas fittings, but have been chosen to harmonise well with them. All the mains and branches have a sectional area of at least 1 square inch per 1,500 sixteen candle-power lamps. There are in all more than 420 lamps of that power, in addition to a few of 8, 32, and 50 candles. The lights were turned on on Saturday evening in the presence of 800 workpeople and visitors, and had a satisfactory run of fully five hours. The whole contract has been carried out by a local form of electricians, Messrs. Lowdon Brothers, to the specification of Prof. Ewing, F.R.S., who has acted as consulting engineer on behalf of Messrs. Paterson and Co. We understand that this pioneer installation will shortly be followed by another of similar size in the same locality.

THE GAS-LIGHT AND COKE COMPANY AND THE ELECTRIC LIGHT.

The half-yearly meetings of the more important gas companies afford the electric lighting interest a favourable opportunity "to see ourselves as others see us." Our readers will therefore probably be interested in the following extracts from the report of the proceedings of the half-yearly general meeting of the Gas-Light and Coke Company, which took place last week. In his opening remarks, Colonel W. T. Makins, M.P., the chairman of the meeting—who, by the way, is entitled "Governor" (not Chairman) of the company—spoke as follows :—

With regard to the electric light, there has been another little flutter over it in the City ; but I cannot find that much capital has been raised. There is a beautiful pamphlet that has been sent out by the House-to-House Electric Light Company ; and I think, from the way it is prepared, that it comes from Mr. Hammond. There is a great deal in it respecting gas ; and I think I have never read a series of statements as to gas more utterly without foundation than those in this little book. When, however, persons have anything to sell, they are not particular as to the terms they employ respecting the article of their rival. There is one thing about the electric light in the City. In comparing the cost of gas and electricity, they take the former at 2s. 5d. instead of 2s. 2d. per 1,000 cubic feet—at which it is now being supplied ; and 3d. represents a considerable difference in making comparisons with the electric light. They say that the cost of electricity is equal to 6s. 6d. per 1,000 cubic feet for gas ; but people who know a great deal about the matter say that 10s. would be nearer the mark if it were thoroughly gone into. However, the electric light people have their sphere, and we have ours ; and I do not think we need be afraid of anything they do or say.

Mr. JACKSON, who followed, said that in respect to street lighting the competition would he believed increase. He had been passing a few weeks in a Midland town, where an Electric Lighting Company, in order to get the introduction of their system into the shops, had supplied the light for nothing ; and their efforts had been attended with immense success—the light surpassing anything that gas could do in regard to showing up articles of refinement in the shops. He thought that such efforts were not

Digitized by Google

to be disregarded by gas companies. The Electric Company he alluded to had laid out £35,000; and their enterprise and energy were shown in their expending this amount on an experiment. In addition to the lighting of the shops, they had put up the light in the main street at their own cost; and they determined to take no steps to obtain custom until the people of the town had satisfied themselves as to the advantages of the light.

A SHAREHOLDER inquired the name of the town which had been referred to by Mr. Jackson where the electric light was in use.

The GOVERNOR: I suppose he means Leamington.

The SHAREHOLDER: Then I have seen the electric light at Leamington many times; and it is anything but a success.

Mr. CARBUTT said that he did not think that the electric light was going to put down gas; but he thought it was well that the Directors should always keep in view the fact that the electric light was a severe competitor. He knew that the Board had taken every means in their power to make themselves acquainted with everything concerning the electric light. Mr. Aird, he believed, had had the electric light laid on in his house; so that he certainly would know what was going on. A paper had recently been read at the Institution of Mechanical Engineers, in which it had been shown that, for the lighting of big works, the arc light could compete with gas lighting. They must therefore, he thought, look to their laurels. He considered that they ought to make experiments as often as was necessary, in order to see what was doing, and what could be done with respect to improving their gas. His impression was, having seen their works, that they need not be frightened about the electric light.

Mr. C. E. JONES (Chesterfield) said that, as one who had had something to do with electricity and being conversant with gasworks all his life, he might observe that where electricity had endeavoured to compete with gas at 2s. 2d. per 1,000 cubic feet for public lighting it had been a failure beneath contempt; and as far as he could see, it was likely to remain so. The great competition that the gas interest had to face was not electricity but oil – oil that paid neither rates nor taxes; oil that was allowed to come into the country duty free; oil that was allowed to be taken from door to door, and respecting which even the machines for its consumption were allowed to come into the country without any duty whatever, whereas gas was taxed, and most iniquitously taxed.

The GOVERNOR, in the course of his reply, said that Mr. Andrews dealt with the electric light at Leamington, and Mr. Carbutt spoke about that matter also. I do not wish in any way to minimise the effect of the electric lighting on gas lighting. All I say is that it is not a direct competitor with us, any more than are wax candles or colza oil lamps. Some people will not burn gas if they can get anything else which does not produce the effects they dislike in the consumption of gas. In that case they will not take gas at any price. We have not a direct competitor in the electric light in that way. But, at the same time, the question of price must come into play; and our reduction of price must tend to throw difficulties in the way of electric lighting companies. I dealt with this book of the House-to-House Electric Lighting Company. The company own to having to charge 6s. 6d., as compared with 2s. 9d. for gas; and that is a very considerable difference between us. I also said that I do not believe in the 6s. 6d.; but there is no doubt whatever about the 2s. 9d. There is another thing which consumers are beginning to find out. Invitations are being sent out to houses similar to the one I occupy; and Mr. Ward has also been asked to be one of 50 to guarantee the consumption of electricity for so many years. It would, however, be a very one-sided guarantee. They do not guarantee to supply the electric light for three years. They are not on the same lines as gas companies. The meter spoken of in this book is exceedingly intricate, and I am not prepared to accept the statement that it is perfectly accurate. When the Board of Trade has testified to its being a perfect meter and have had time to consider it, and when the electric light companies are put under the same restrictions as the gas companies, they may fairly ask to compete with us. I notice that Lord Thurlow and Major Flood Page state that they are prepared to accept the restrictions put on gas companies. If that is the case, *cadit quæstio*. I do not suppose we should have any *locus standi* to oppose them.

THE ELECTRIC LIGHTING OF ST. JAMES'S, WESTMINSTER.

Report of the Lighting Committee of the Vestry of the Parish of St. James, Westminster, on the Draft South Metropolitan Electric Lighting Order.

Your committee have to report that they have given very careful consideration to the clauses of this draft order.

Throughout their deliberations they have endeavoured to keep in view the interests of the general body of consumers of electricity, and the rights to be maintained by the vestry on behalf of the public, such as the uninterrupted use of the streets for traffic, and at the same time to bear in mind that any undue restrictions would probably interfere with the working of the order on commercial principles, and therefore indirectly affect prejudicially the interests of the consumers. A new undertaking, such as the supply of electricity from a central station, must necessarily pass through an experimental stage, and until sufficient knowledge has been gained by actual experience of the operation of a Provisional Order under the Electric Lighting Act, it is evident that the full effect of many of the clauses of the draft order under consideration is to some extent merely speculative.

Some of the conditions which the undertakers seek to attach to a right to require a supply of electricity are so onerous as to be almost prohibitory in character. Thus by Clause 20 the undertakers propose that they shall not be compelled to supply electricity to any private consumer in a street where a main has not been laid, unless six or more owners or occupiers of property in such street enter into an agreement, binding them to pay for a period of three years such a sum as will represent twenty per cent. per annum upon the cost of laying such distributing and other mains as may be necessary. In addition to this agreement, however, the would-be consumer may be required by Clause 41, after a distributing main has been brought within twenty-five yards of his premises, to enter into a written contract to receive and pay for a supply of electricity for a period of two years, of such an amount as to be equivalent to a return of not less than twenty per cent. per annum on the outlay incurred in providing any electric line that may be necessary. Your committee are of opinion that if the Company obtain their Provisional Order and attempt to enforce such conditions as these to any large extent, the general introduction of electricity for the purpose either of light or power, will be relegated to the very distant future. Such being the case, it would appear to be an act of wisdom if the undertakers were to eliminate all such prohibitory conditions from the order, and afford all possible facilities for the introduction of the new means of lighting.

One very important point to which your committee have directed their attention is the possibility of the gas company's undertaking eventually proving less remunerative in the poorer portion of the parish, owing to the withdrawal of the larger consumers in the principal streets, to whom expense may not be so much an object as the greater cleanliness and coolness which are anticipated from the adoption of the electric light. In that case the mains would have to be charged with gas as at present, and it is evident that the area and cost of distribution would be proportionately increased as the length of unprofitable mains extended. In such a case, the price of gas would probably rise, and the increased cost would mainly fall upon the consumer in the poorer localities. It is, indeed, possible for the poorer locality to be deprived both of gas and electricity, for under the provisions of the Electric Lighting Act the Board of Trade may relieve a gas company of their obligation to supply gas in an area sufficiently supplied with the electric light, if such area has become unremunerative, while the price of electricity and the conditions attached to its supply may be a serious impediment to small householders. This contingency may be remote, nevertheless your committee think the point of such importance as to deserve the consideration of the Vestry and to engage the attention of the Board of Trade.

The order differs in one or two material particulars from the Edison Order of 1883 (since revoked), which may for all practical purposes be regarded as the model order of the Board of Trade. For instance, only one area of supply is now spoken of, instead of two as formerly, one a compulsory and one an optional area. No streets are now specified in which mains are to be laid as a matter of course, but a main is to be laid in any street in any part of the area, either on the requisition of private consumers or of the local authority (Clause 19). The committee are inclined to think that the adoption of only one area of supply and the omission of specified streets is an improvement, inasmuch as it places the whole area and every street contained in it upon an equal footing, and allows the undertakers free scope to develop the undertaking on a purely commercial basis.

Taking in numerical order those clauses which require alteration, your committee are of opinion and recommend that the Board of Trade should be requested to amend the draft order in the following respects:—

Clause 4.—The capital of the undertakers is stated at £250,000. Your committee are of opinion that this sum is utterly inadequate to carry out the obligations of the order in so large an area as is proposed, unless the undertakers have taken power in their Articles of Association to largely increase their capital, and that the attention of the Board of Trade should be directed to this subject, with a view to their taking any additional guarantee they may consider necessary when the order becomes operative. Your committee would view with great disfavour any attempt to form a company for the purpose of obtaining a concession, so to speak, for the supply of electricity in a large area of supply, with insufficient capital, with the intention of subdividing the area into districts, each to be supplied by a company floated by the original undertakers.

Clause 5.—The area of supply is an irregular oval or oblong, extending from Shaftesbury-avenue, at its junction with Broad-street, to Lower-marsh, Lambeth, in one direction, and from the eastern end of the Green Park to Bridge-street, Blackfriars, in the other. The northern part of the parish is excluded from the area of supply, and being limited in extent, and, speaking generally, of a poorer character than the Pall-mall district, it could not profitably be formed into an independent area of supply, and would therefore stand at a considerable disadvantage. Your committee therefore recommend that the order be opposed as a whole unless the undertakers consent to alter the boundary line of the proposed area of supply so as to comprise the whole extent of the parish within its limits.

Clause 9.—By the second paragraph of this clause, the undertakers would acquire large powers, apparently involving a frequent if not constant interruption of traffic, and your committee recommend that the clause be amended so as to better define and limit the powers of the undertakers in the use of their distributing boxes laid in public streets, or to restrict such use to hours when the streets are least used for traffic.

Clause 10.—By this clause, the undertakers are required to give one month's notice of their intention to carry out works involving the disturbance of the surface of a street, but no part of the month of August is to be included in calculating that period. Having regard to the fact that many local authorities do not resume their meetings until towards the end of September, your committee recommend that the clause be amended to read "no part of the months of August and September shall be included."

Digitized by Google

Clause 11.—The undertakers seek power either to pay or secure compensation for disturbance in streets not repairable by local authorities. This proposal seems to be too ambiguous to be satisfactory, and your committee recommend that the words "secured," "securing," and "secure," be omitted from sub-sections (A) and (E), and the clause amended accordingly.

Clauses 12 and 13.—This clause as drawn prohibits interference with sewers vested in the Metropolitan Board of Works. Sewers vested in the vestry would probably be usually protected by a previous clause (10), but as that clause might not meet all cases, Clause 12 should be amended by inserting after Metropolitan Board of Works the words "or part of any sewer vested in any vestry or district board of works." Clause 13 should be amended in the same manner, and also by the insertion of the words "or to such vestry or district board of works" in line 20.

Clause 17.—It is difficult to realise the full import of the words "after the expiration of the period of two years" at the commencement of this clause. Apparently, the undertakers might occupy the field for two years without coming under any obligation to even commence the installation. Possibly the undertakers may urge that two years will not be too long to establish and equip the lighting station or stations required, but the power reserved to the Board of Trade in the latter part of the clause seems amply sufficient to meet such a case. It is doubtful, moreover, whether the undertakers could lawfully lay a main in a street until after the expiration of two years, however willing they might be to do so, if the clause remains as drawn. Your committee therefore recommend that the words "after the expiration of the period of two years" be omitted. The penalty for making default in laying mains is specified in the following clause.

Clause 18.—If the undertakers make default in laying down mains within the time prescribed by the Board of Trade under the 17th clause, the Board may, upon the application of the vestry, revoke the order in whole or in part, or may suffer the order to remain in force, subject to such conditions as they think fit to impose, and these conditions will be binding upon the undertakers. The undertakers propose that their consent should be necessary before the Board of Trade can revoke the order as to part of the area of supply, on the failure of the undertakers to lay down mains, although they assent to the Board possessing absolute power to revoke the order as a whole. Your committee are at a loss to appreciate this distinction, and therefore recommend that the words "(with the consent of the undertakers)" be omitted.

Clause 20.—In line 28, the word "five" should be altered to "three," to correspond with line 14. Three years is proposed as the period for which the undertakers may require a consumer to enter into a contract to take electricity, before they are compelled to lay a distributing main. By this clause the undertakers may require six or more persons severally to enter into an agreement to pay for a supply of electricity for a period of three years; this provision might saddle one party with the whole cost of the supply of electricity to all the persons party to the agreement. Your committee therefore recommend that the clause be amended by the addition of the following words:—"Provided that no person executing such agreement shall thereby become liable for payment of any amount beyond his proportionate share of the amount specified to be paid in such agreement, having regard to the number of persons party to such agreement, and the quantity of electricity supplied to each of such persons."

Clause 21.—Under this clause, the local authority may be required to enter into an agreement to take electricity for lighting public lamps for a period of three years. Your committee are of opinion that the 48th clause, which regulates the price of electricity supplied to public lamps, according to circumstances, including the cost of mains and wires specially laid, fully meets the case, and therefore recommend that Clause 21 be omitted.

Clause 41.—This clause restricts the supply of electricity to premises within twenty-five yards from any main already laid, and is not consistent with the 20th clause. In the opinion of your committee this clause (the 41st) should be omitted altogether, and the provision made therein for regulating the laying of service mains incorporated with the 20th clause, or if the clause is allowed to remain, the words "within the area of supply" should be substituted for "within twenty-five yards from any main of the undertakers." The clause requires further amendment in that provision which fixes 20 per cent. per annum on the cost of service lines as a minimum charge, apparently leaving the undertakers full liberty to fix any proportion they please as a maximum. The words "not less than twenty pounds per centum" should be omitted, and the words "not more than twenty pounds per centum" inserted in lieu thereof. A third amendment in this clause is also required; the undertakers seek power to take security, after they have given a supply of electricity, for the payment of all moneys which may from time to time become due in respect of such supply. Your committee think this provision might prove needlessly irksome, and recommend that the words "from time to time" in line 20 be omitted, and that the words "during the then current quarter" be inserted after the word "supply" in line 20, so as to limit the power of the undertakers to require payment in advance for the current quarter only.

Clause 43.—Gas companies are required to light public lamps if they are not more than 75 yards apart. The undertakers seek to impose a limit of 50 yards from a main in the case of public lamps. Your committee are of opinion that the undertakers should be required to supply public lamps with electricity if they are within seventy-five yards of a main, and recommend that the clause be amended accordingly.

Clause 45.—Both the Board of Trade and the vestry have hitherto regarded supply by meter as the most satisfactory method to adopt in principle. In the absence, however, of any completely satisfactory meter, it is evident that other modes of supply must be adopted, at least as a temporary measure. Perhaps it would be well to recognise supply by meter as the method to be ultimately adopted, by adding at the end of the clause some such words as these: "In the event of the undertakers adopting more than one method at the same time as the basis of charge in any portion of the area of supply, any consumer in such portion of the area of supply may elect by which method he shall be charged." And your committee recommend accordingly.

Clause 55.—By this clause the undertakers take power to let meters. Words should be added declaring that the meters and fittings are not subject to distraint. The clause relating to gas meters (10 Vic., cap. 15, sec. 14) might be adapted.

Clause 63 (B).—This portion of the clause might lead to the elimination of a poor district, and if the supply of gas should then be carried on without profit in that district, and withdrawn under the provisions of the Electric Lighting Act, some hardship might result. However, the consent of the Board of Trade is required to make this clause operative, and bearing in mind the attention the Board has hitherto paid to the representations of the local authorities on the subject of electric lighting, there is perhaps little to fear that the provision will be allowed to operate prejudicially to the poorer classes. Your committee, however, think that the attention of the Board should be specially directed to this point.

Clause 69.—The proposal to constitute the Board of Trade a court of first instance between a complainant and a Court of Summary Jurisdiction is open to objection, and your committee recommend that all words after the word "jurisdiction," in line 11, be omitted.

Your committee have not attempted to deal with any technical questions, such as are dealt with in Clauses 8 and 60, but, as on former occasions, leave these to be decided by the Board of Trade, acting upon the advice of experts.

Your committee recommend that a copy of this report (supposing the same to be adopted by the vestry) be forwarded to the Board of Trade as embodying the representations which the vestry are desirous of making on the draft order in question, and of the objections which they take thereto; that a copy be sent to Messrs. Bircham and Co., parliamentary agents for the order; and that a copy be also sent to the Metropolitan Board of Works, in reply to the enquiry of their engineer as to the nature of the objections (if any) which the vestry take to the draft order.

All which your committee beg to submit.

(Signed) WILLIAM JENKINS, Chairman.

COMPANIES' MEETINGS & REPORTS.

The Submarine Telegraph Company.

The half-yearly meeting of the proprietors in this Company was held at the office of the Company, 2, Throgmorton-avenue, London-wall, on Tuesday last, the Hon. H. R. Brand presiding.

The Secretary (Mr. S. M. Claro) having read the notice convening the meeting,

The Chairman said: Gentlemen, I presume that I may, as usual, take the report as read. In moving the adoption of the report and accounts I have in the first place to express the regret of the Board at the absence of our Chairman, Sir Julian Goldsmid. He is passing the winter abroad, and he desires me to state that it has been a great disappointment to him to find that he is not able to attend here to-day. In his absence the Board have deputed me to take the chair because I happen to have been associated with the Chairman in negotiations with the English Government on matters which seriously affect the interests of this Company. I need not detain you on the accounts for the present half year. They are very simple and normal in their character. Perhaps the only item that calls for any special remark is that of salaries and wages, which show a considerable increase. The moiety of that increase is explained by the fact that there have been 27 pay days, whereas the takings have been for only 26 weeks. The balance of that increase is explained by the necessary and inevitable increase in the salaries. There is nothing unusual in the character of the business, which has been very steady and subject to very little fluctuation. On the one hand there has been a considerable increase in the number of messages, but on the other hand there has been a shrinkage in the number of words per message. The result of that is that there has been a slight increase in the amount of receipts this half year as compared with the corresponding half of last year. The accounts, however, will enable the Directors to recommend a dividend at the rate of 15½ per cent. per annum, to allocate the usual amount to reserve fund, and to carry forward a small sum. Now I am quite sure that your minds at this meeting are occupied with matters affecting the existence of the Company, and therefore I will shortly inform you of our position in respect to the renewal of our concessions. You will remember that on two or three of the last occasions of our meeting the shareholders, the chairman deprecated any discussion upon this question. You were, however, quite willing to follow that advice, and it was obvious that no advantage could be gained by making public the course of our negotiations with the French Government. At the same time I think I am right in saying that the Chairman, in guarded language, expressed an expectation that we should be successful in obtaining a renewal of this concession from the French Government. Well, I have to say that the Chairman was perfectly justified in expressing that opinion. We had actually received an intimation from the French Government, of which M. Rouvier was the Premier, that the renewal of the concession would be granted to us by the French Government for a term of years upon terms agreed upon between the Government and the Company, when the English Government interposed, and requested the French Minister to defer signing that agreement until he had had an opportunity of considering an alternative policy of the English Government to place the administration and working of the cables between England and Belgium and between England and France in the hands of the Governments of the respective countries. Well, now, I think it right to say here that our success so far was due to the energy and the ability of our Chairman and of Sir James Carmichael, one of our colleagues, ably seconded as they were by Count Dillon in Paris, who spared no effort in the interests of the Company. I think it right that the shareholders should know this, because these gentlemen did all that was possible, and they could not by any chance have foreseen the very strange—I think the very strange—action of the English Government. We consider that the action of the English Government is a breach of faith with the Company. We have pressed this point on their attention, but Governments have no consciences. In a matter of this sort they seem to be all alike. We have now a Chancellor of the Exchequer who is a financier and a man of business, and he has seen, as he thinks, an opportunity of obtaining what he believes to be a profitable business upon easy terms, and has seized that opportunity; but I think he can only effect his object at the sacrifice of your interests. Well now, if it were said that this was for the public advantage something might be said for the policy adopted, but it is not for the public advantage. The public can get every advantage from this Company that the Post Office could give them. It is a mistake to suppose that the tariffs have been settled by this Company; they have been settled by the Governments with the agreement of the Company. The Company have been always anxious to meet the wishes of the Government in this matter, and of course they would not object to a reduction of tariffs so long as it did not preclude the Company from carrying on their business in a profitable way. The policy of the Government is not likely to encourage or stimulate enterprise. Our late Chairman, Sir James Carmichael, and the other concessionaires were the pioneers of submarine telegraphy in this country. I am right, I believe, in saying that the Calais cable of this Company was the first cable ever laid under the sea. The enterprise was at the time considered to be a mad and hopeless one, yet the Company, instead of failing, succeeded, and now they are required to yield up the result of their skill and enterprise. Well now, I have said that this is a gross breach of faith on the part of the Government, and I will tell you why I say so. In 1868, when the English Government purchased the inland telegraphs, this Company entered into a working agreement with the Government for the transmission of messages along the land lines. Ten years later the Government—that is to say, the Post Office—being desirous of better terms entered into a fresh agreement with this Company, by which on the one hand the Government invited the Company to

Digitized by Google

obtain a renewal of the concessions from the French and Belgian Governments, and on the other hand the Company undertook, as soon as they obtained a renewal of those concessions, to give terms to the Post Office more advantageous than those fixed by the agreement of 1868. Well now, the Government allege that this agreement must be null and void by the failure of the Board to obtain an earlier renewal of the concession from the French Government and by lapse of time. Now, in the first place I have to say that our failure to obtain an earlier renewal of the concession from the French Government was not owing to any fault of the Board, but to the fact that we were always met with a refusal by the French Government to enter into the consideration of this matter until the time of the expiry of the old concession had arrived. But apart from this, the lapse of time and the failure to obtain an earlier renewal of the concession were no justification for the action of the English Government. They entered into the agreement of 1878. They invited us to obtain a renewal of the concession from the French Government, and from that time until last November they never intimated to the Company that not only was the agreement cancelled but that they intended actively to oppose the renewal of our concessions. I contend that for all those years they led the Board to believe—and the Board acted on the belief—that the position of the Government would be one of benevolent neutrality. We have urged this point on the Government, and have intimated to them that if they insist upon this policy they ought to have regard to these circumstances in fixing the price to be paid to this Company. We have done this because it is obviously absurd for the Company to discuss any longer the question of policy with Her Majesty's Government. We understand that the Cabinet has decided the question of policy, and so far the question must be considered to be settled as regards the English Executive. There remains, of course, the decision of the French Government, who have come to no conclusion on the matter, and there remains also the decision that the English Parliament will come to on the subject. I hope for my part that some efforts will be made in Parliament to point out the extreme danger of these extensions of Government business. Fortunately there are very few technical departments of the English Government. I have had experience in some of them. The course of action in those departments is always the same. The permanent officials believe, or profess to believe, that they can carry on business better than it can be conducted by private enterprise. In that they are mistaken. They are for ever endeavouring to extend the area of their departments, and they put forward such proposals on the ground that they will be for the public advantage, so that the Minister making himself responsible for these extensions will get a great access of popularity, whereas the only practical result is a large increase of the pension and salary lists, and probably an increase in C.B. and K.C.B.-ships. It seems that the Treasury are quite incapable of resisting this tendency, although they know, from experience, what is the result. They have had a bitter experience in the past. There is an enormous deficit upon the telegraph account. Take the Parcels and Samples Post of the Post Office, and it will be found that that department publishes no balance-sheet. I think that some member of the House of Commons ought to call for a return of the Parcels and Sample Post. If they got that return it would be found that the business is conducted at a ruinous loss to the taxpayer, and if they absorb the telegraph companies they will soon be conducting that business not at a profit but at a loss. As I have said before, it is useless for us to discuss the question of policy with the English Government. If they obtain the assent of the French Government, the only question between the Company and the Government will be one of terms. I cannot express myself as being very sanguine that the terms will be such that you and the Board will consider highly satisfactory ; but I am happy to say that we have got the Government to assent to two principles for which the Directors have contended, and to which they attach the utmost importance. I do not think I ought to say more at the present moment. I can only ask you to have patience, and to be assured that the Directors will do their best to guard your interests, and that so soon as we approach nearer to a settlement we will call you together to obtain your decision. He concluded by formally moving the adoption of the report and accounts.

The Hon. Ashley Ponsonby seconded the motion.

Mr. King thought that the Chairman had so ably stated the position of matters that any remarks a shareholder might make must be almost superfluous. Nevertheless, having for many years been interested in this Company, he could not help calling to their recollection a remark he had made at one of their meetings in bygone days to the effect that if they did their work well, and served the country well, he for one would have nothing to fear as to the renewal of the concession. He believed at that time that it was quite impossible for a Company that had manifested the indomitable enterprise of this Company, and that had brought to a practical use to the country at large such an invaluable invention as submarine telegraphy, to be deprived of its rights. This was the pioneer company, and if it had not been for the courage of its originators submarine telegraphy might have been unknown to the commercial world. For that reason he felt so certain that they should at least have justice at the end of the concessions that he ventured to make the remark—and he would still fain believe it—that they would have justice done to them by the English Government. If the British Government were desirous to make the property their own, they must in all conscience give the company a fair and reasonable remuneration for taking it into their own hands. As had been intimated by the Chairman, there was the Parliament of the country, before which they might lay their claim, and he for one would await with anxiety its verdict. After the enterprise displayed by the promoters of the Company in the earlier stages of its existence, it was indeed a very poor reward to them to find that the Government, by intimation that had been given through the press and before the negotiations had ripened, had published information which had considerably damaged the property by depressing its value in the market, and very unnecessarily aggravated their position.

Mr. Soden said he was sure that the shareholders must have listened with great satisfaction to what had been said by the Chairman, who he believed would have their entire sympathy. He thought he might show his fellow shareholders in what way they might support the Board. He would say very little about the policy of the Government in their endeavour to acquire submarine communication between the Continent in the same way as they had acquired the inland telegraphs within the limits of the United Kingdom ; but he was completely staggered when he heard, if rumours were true, of the means adopted by the English Government to induce the French not to renew the concession of the Company. He was quite sure that the English taxpayers would not submit to have their money spent in backing up the credit of a foreign Government, and in allowing them to have more than their fair share of the profit of the undertaking. Assuming it to be a right policy, in what way could they as shareholders assist the Board and see that they got a fair and adequate remuneration for their business and property ? He would make this remark in passing with regard to the policy of the Government. It did seem to him that it would have been a more prudent thing if the Government, instead of embarking on risks for foreign Governments by the acquisition of submarine telegraphy, considering the present state of the Continent if war were to break out, were to leave such matters in the hands of a Company like theirs, which might act as a buffer between this country and foreign Governments in the event of any complications. Assuming that Parliament sanctioned this policy, however, and that it was a right thing for this country that it should acquire the business and property of submarine cables between this kingdom and the Continent, they must look around and see whether they had not some supporters in the same interests as they had. He ventured to think that they had. He read with some regret the fact that Her Majesty's Government had arbitrarily given notice of their intention to revoke the license that they now held and had held for nearly thirty years for the use of the foreshore. He would call the attention of his fellow shareholders to the fact that every cable company carrying on the business of submarine telegraphy between this country and every part of the globe held its title in the same way as this Company. The Anglo-American, the Eastern, and other companies were in the same position. He would point also to this fact—and he was well within the mark—that the cable mileage of all the companies carrying on the business of submarine telegraphy beyond the limits of the United Kingdom was over 100,000 miles, a greater mileage than that of the railways of the United Kingdom; and of course it was obvious that millions of money had been embarked in the industry. Now, had they not any supporters to help them? It might appear that the Government, if they saw fit, for any purpose of their own, looking at the way in which they had obstructed the Board in their endeavours to get a renewal of their concession, would give to any one of those companies three months' notice of their intention to revoke its license. It would mean the destruction of their trade and the loss of their capital should this policy of the Government in its integrity be carried out. Therefore, let the shareholders combine with those companies ; let them show to those companies that they were exactly in a similar position to themselves. Thirty years ago they embarked their capital in this undertaking when very little was known of the science, when it cost very much more to lay cables, and when risks were run which were now thought nothing at all about. By the employment of that capital, by the skill and energy of those gentlemen who had conducted their affairs, they had created a business for themselves (because there was nobody else in the field) which at the present moment, in round numbers, was worth £150,000 a year. Was, then, the Government of this country to take and put into their pockets that annual sum, which was capable of extension, without paying the Company full and adequate compensation? If they did, they would be acting upon the principle that might was right. Let them unite with all submarine cable companies who were doing business to other places than the Continent to resist such a policy. They should then be able to demand justice at the hands of the Government. What took place with regard to the inland telegraphs ? They were really in a very similar position to themselves, and he thought this was a very important point. Speaking broadly, the inland telegraph companies, by leave of the railway companies, by leave of the canal companies, and by leave of the road authorities, laid down their posts along the side of the railways or the banks of the canals, and were subject to have their wayleave revoked by any of these interests. Now, it was said that the Government were very foolish in those days—whether they were it was not for him to say—in not going to those companies in the first instance ; but it seemed to him that because they were foolish on that occasion they were not justified in adopting their proposed policy against this Company. When it was seen that the inland companies were not to get fair compensation, what did they do ? They combined together and got it. It might be that the country paid too dearly for the telegraph system, but that was no reason why the Government should commit an act of injustice now, and therefore let them ally themselves with the other submarine cable companies, and let them show the Government that they were not to take the property of the Company without paying them adequate compensation.

The Chairman said he was obliged to the two shareholders for their speeches, and especially for the suggestion with regard to the interests of the other companies. It was certainly true, he thought, that the blow aimed at this Company was one which showed that the other companies were exposed to a similar danger.—The motion was agreed to unanimously.

A resolution was afterwards passed declaring the dividend recommended at the rate of 15½ per cent. per annum.

Digitized by Google

On the motion of Mr. SODEN, seconded by Mr. KING, a vote of thanks was accorded to the Chairman and the Directors for their conduct of the Company's business during the past half year.

The CHAIRMAN briefly replied, and repeated his expression of the hope of the Board that the shareholders would do everything in their power to strengthen the hands of the Directors in their efforts to see justice done to the Company.

The proceedings then terminated.

Taunton Electric Lighting Company (Limited).

The first annual general meeting of the shareholders of this Company was held last week at the Castle Hotel, Taunton, under the presidency of Mr. W. H. Fowler.

The CHAIRMAN moved and Councillor POTTER seconded the adoption of the following report of the Directors:—

The number of shares allotted is 873, on which the sum of £4,365 has been received, including the amount allotted on account of the purchase of the business. The number of private customers is now 20, besides the town lighting, and the number of arc lamps let at a rental is 65, besides the incandescent lamps in use, numbering 200. The accounts for the year show a profit of £315. 15s. 5d. The Directors recommend that a dividend of 5 per cent. be paid, free of income-tax. This will take £191. 19s. 6d., leaving a balance of £123. 15s. 11d. to be carried on for a reserve and depreciation account. In addition to the Taunton business the Company has carried out temporary installations at Bath, Weston-super-Mare, and Exeter. Deputations from various places have visited Taunton during the past year for the purpose of inspecting the Company's works, machinery, and the lighting arrangements of the town, the general testimony being that it is one of the most successful installations yet carried out in the United Kingdom. The machinery has been maintained in excellent working order, the repairs being charged to income account. As the demand for the light increases, it is expedient to lay down more plant and machinery, and to enable the Directors to do this they hope that the public generally will take up more shares to increase the capital available for this purpose. Two of the Directors retire by rotation, and are eligible for re-election.

After some general discussion the report was agreed to.

Mr. Sampson and Mr. Lewis, the retiring Directors, were re-elected, and Mr. J. A. Winter and Mr. C. E. Lance were appointed additional Directors, the number being increased to nine. Mr. Massingham was re-appointed Managing Director, and Mr. A. Goodman auditor.

Mr. BALE proposed the re-election of Mr. Massingham as managing director. The position of Mr. Massingham upon their Board was a unique one. He discharged the onerous and important duties of a managing director in a very satisfactory way to the shareholders, and he was sure the dividend that had been declared that night as the result of the first year's working would meet with the approval of every shareholder. To this result Mr. Massingham's able management had very largely contributed.

The proceedings then terminated.

India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

Report of the Directors for the year ended December 31st, 1887, to be presented at the twenty-fourth ordinary general meeting of the shareholders, to be held at the Cannon-street Hotel, on Tuesday, the 28th inst., at 12 o'clock:—

The accounts show the net profit for the past year to be £13,174. 10s. Adding £37,955. 13s. 5d. brought forward, and deducting £20,800 interim dividend paid in July, there remains a disposable balance of £30,330. 3s. 5d. The Directors recommend the distribution of a dividend of 10s. per share, free of income tax, amounting to £20,800, making, with the interim dividend, a total payment for the year of 10 per cent., and leaving £9,530. 3s. 5d. to be carried forward.

The Company has done an increased general business in the year; but competition and cost of raw materials have also increased, and have kept down the rate of profit on manufactured goods. The little submarine cable business open to tender has been keenly competed for. The contracts secured by the Company have given inadequate employment to its cable works and steamers during the year; and the expense of the submarine telegraph engineering staff and plant, though reduced as far as prudently could be, has borne heavily on the general earnings. To these causes the Directors attribute the reduction in profit shown in the accounts. In order, however, to equalise dividends to some extent, and believing that they may hope for better results in the future, they have drawn upon the floating balance of undivided profit, still leaving a substantial amount to carry forward to the current year. The Company's works, machinery, and vessels are all in first-rate order.

Mr. Silver and Mr. Bannatyne, the Directors retiring by rotation, offer themselves for re-election.

Brighton Electric Light Company (Limited).

Second annual report of the Company's operations for the fifteen months ended 31st December, 1887, to be presented at the third ordinary general meeting of the shareholders to be held at the offices of the Company, Gloucester-road, Brighton, on Saturday, the 18th inst., at 5 p.m.

1. The Directors submit to the shareholders the report of the operations of the Company from the 1st October, 1886, to the 31st December, 1887.

2. The capital account has, during this period, been augmented by the sum of £2,100, which has enabled the Company to increase their engine power and dynamo capacity, and to largely extend the circuits. The profit and loss account, after writing off the special legal expenses of the year, and an ample sum for depreciation of plant, shows a balance of profit for the fifteen months of £721. 16s. 6d., which, with the small balance brought forward from last year's accounts, makes the sum to the credit of profit and loss account £729. 0s. 11d., and the Directors recommend the following appropriation of it:—

	£	s.	d.
Dividend of 5 per cent. per annum on the share capital	568	16	10
Liquidation of the balance of the preliminary expenses account	89	16	2
Carried forward to next year's profit and loss account	70	7	11
	£729	0	11

3. There has been a steady increase in the Company's business during the period under review. The mains belonging to the Company now extend a distance of fifteen miles, reaching westward as far as King's-gardens, Hove; eastward as far as Eastern-terrace, Kemp Town; and northward as far as Hanover-crescent, Lewes-road.

4. One reason of this increase of business, and of the probability of its further development, is the extension of the Company's mains into Hove. As that district consists almost entirely of the residences of the wealthy, a practically unlimited field is thereby opened to the Company.

5. The Directors have considered it desirable, in order to be in a position to cope with their increasing business, to still further increase the dynamo power, to extend the Company's circuits, and to gradually place "converters" in all the premises lighted, by means of which it will be possible to turn lights on and off one by one when required.

6. The cost of the proposed extensions will be about £2,000, and the Directors propose to cover this sum by a further issue of share capital. Preference will be given to applications received from residents in Brighton and Hove, especially from those who are customers of the Company, as the Directors are anxious to widen the local interest in the concern.

7. The contemplated addition to the plant will bring up the total dynamo capacity to over 2,500 sixteen candle-power incandescent lamps, the present engine-power being capable of driving dynamos for 3,500 lamps; so that the capacity of the plant can be enlarged to this extent by the addition of new dynamos at any time when required.

8. The nature of the improvement in the Company's business may be seen by the following statements:—

(a) Lights in operation on:—

	Arcs.	Incandescents.
October 1st, 1885	34	516
,, ,, 1886	27	875
December 31st, 1887..........................	34	1,372

(b) Quantities of electricity supplied from the works during the past fifteen months, as compared with corresponding months of previous year

UNITS SUPPLIED.

1886.	In former period.	In present period.	Percentage of inc.
October......	1,269	2,633	108%
November...	2,117	2,984	41
December...	2,446	3,175	30
1887.			
January ...	2,138	3,111	46
February ...	1,587	2,180	38
March	1,190	1,936	63
April.........	1,035	1,639	58
May	971	1,031	7
June	703	1,016	45
July	701	1,093	56
August	1,462	1,845	26
September..	1,846	2,909	63
October ...	2,633	3,958	50
November...	2,984	5,427	81
December...	3,175	6,372	101
Totals...	26,257	41,309	56%

9. It will be noticed that, whereas the total business shows the satisfactory increase of 41,309 units as compared with 26,257 in the former period of fifteen months, the most recent improvement is still more marked; the units consumed in December, 1887, being 6,372, as against 3,175 in December, 1886, and the consumption in the quarter ended December 31st, 1887, 15,757 units, as compared with 8,795 units in the corresponding quarter of 1886.

10. In view of these figures the Directors feel confident that, with the proposed additional machinery at their command, they will be able, during the current year, to considerably augment their gross receipts, and as the expenses will not grow in anything like the same proportion, a substantial improvement in the profits will in their opinion result.

12. Mr. Arthur Wright, who, while in the employ of Messrs. Hammond and Co., started the works at Brighton in conjunction with Mr. Robert Hammond, and who has brought them to their present state of efficiency, has continued to act as managing director; and the thanks of the shareholders are due him for the highly satisfactory manner in which he has conducted the business of the Company during the period under review.

13. He reports that the engines and dynamos have continued to give satisfaction, and are at the present time in thoroughly good working order. There has not been one single breakdown of the machinery during the fifteen months. The whole installation is in a much higher state of efficiency than it was at the date of the last report.

14. The meeting will elect an auditor or auditors for the ensuing year.

Digitized by Google

Swan United Electric Light Company (Limited).

Fifth annual report of the Directors, to be presented at the ordinary general meeting of the Company, to be held at the Cannon-street Hotel, on Tuesday, the 28th inst., at 12 o'clock :--

1. The accounts presented are for the year ended September 30, 1887.
2. The business has grown, and has resulted, after paying all current charges, and making fair allowance for depreciation of plant and machinery, in leaving a sum of £7,554. 11s., which the Directors recommend shall be applied to the writing off of £5,834. 3s. 1., the amount which stands against profit and loss, carrying forward £1,720. 7s. 11d.
3. The Directors have resumed negotiations with the Compagnie Continentale Edison, with a view of arriving at an equitable settlement in the countries in which they hold patents in connection with electric lamps. Should these negotiations result in any plan which the Directors regard as beneficial for the Company, they will call a special meeting of the shareholders.
4. In their last report the Directors stated that they were led to believe that a decision in the patent suit would shortly be given by the judges in the Court in Berlin. The case has dragged on during the year, but judgment has not yet been delivered.
5. Competition is very keen on the Continent, but the Swan lamp is undoubtedly the best in the market. The sales have increased during the year considerably, and the demand for lamps during the winter months has been largely in excess of previous years.
6. The Directors who retire by rotation are Mr. F. R. Leyland and Mr. W. C. Quilter, M.P., who, being eligible, offer themselves for re-election.
7. Messrs. Quilter, Welton and Co. will offer themselves for re-election as auditors.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 3rd February amounted to £2,730, and for the week ended February 10th to £3,856.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY. - The traffic receipts of this company for the week ended February 10th (after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company) were £2,559.

NEW COMPANY REGISTERED.

ECLIPSE ELECTRIC LIGHTING SYNDICATE (LIMITED).—Registered by Ernest Wood, 4, Broad-street-buildings, E.C., with a capital of £20,000, divided into 20,000 shares of £1 each. Object, to carry into effect an agreement dated February 4, 1888, and made between John Garford, of the one part, and Willoughby Hamilton Tower, as trustee on behalf of the company, of the other part, to purchase and acquire the inventor's letters patent, &c. ; to carry on business as an electric light company in all its branches. The first subscribers are :—

	Shares.
J. Garford, 3, Vernon-chambers, W.C.	1
J. Robinson, 60, Gresham-street, E.C.	1
W. H. Powes, Silverdale, Kent	1
W. C. Loe, Isleworth	1
H. Martyn, 68, Leadenhall-street, E.C.	1
H. E. Robinson, 11, Poultry, E.C.	1

The business of the company shall be managed by the board of directors, whose number shall not exceed nine nor be less than three. The first shall be Sir Charles Clifford, Bart. ; John Garford, Esq. ; and Valentine Robinson. The qualification of a director shall be the holding in his own right 200 shares of £1 each, and by way of remuneration they shall be paid for their services the sum of £150 per annum. The regulations of Table A in the first schedule to the Companies Act, 1862, do not apply to this company.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 510.—Vol. XX. FRIDAY, FEBRUARY 24, 1888. Price 4d.

NOTES.

We deal with the general question of the City lighting fiasco in our leading article, but we should like in this place to ask for some further information (if this be not too bold) about the Maxim-Weston 450 candle-power arc lamp. It appears that this company are willing to supply 800 of these lamps for the sum of £3,875 per annum—that is, a little less than £4. 17s. 0d. per lamp. Now, the lighting is to be from sunset to sunrise, which, allowing nothing for fogs, is equivalent to 4,300 hours per annum. At £4. 17s. 0d. per lamp, this makes 0·27d. per lamp-hour, which we should have thought would have been somewhere about the cost of current *alone*. Or, taking another view, this figure very nearly represents the cost of carbons for a Brush 2,000 candle-power lamp; but we may assume that for the smaller Maxim-Weston lamp the cost is less than one-half this, or, say, ⅛d. per lamp-hour. We have, then, a trifle over ⅛d. per lamp-hour left, and out of this the company will have to pay the whole of the central station charges, to say nothing of office expenses, directors' fees, &c., &c. If this is, indeed, a *bona fide* offer on the part of the company we greatly fear that it is the result of some miscalculation, such as that which seems, if local reports are correct, to have occurred in connection with their contract for the Brighton Pavilion lighting.

The Submarine Telegraph Company, besides being unlucky in its recent negotiations with the French Government, has been equally unfortunate in creating enemies on this side the Channel, or at all events in not taking pains to secure friends. The management seems to have gone on its own way in a rather blind fashion, regardless of the chances which 1889 would bring, thinking apparently that if France was made easy all would be well. The result is that not only are the Governments of Great Britain, Germany, and Belgium arrayed against the monopoly, but the British press is distinctly hostile. With regard to the latter a great deal of heedless and ungenerous language is used about the Company, its rich earnings in the past being treated as a sufficient reason for summarily extinguishing them altogether.

As to this we would remark that, although on public grounds the cables connecting England with the continent of Europe should no longer remain in private hands, the process of transfer to the respective Governments involves not merely the termination of a monopoly, but the extinction of its business even as a competitor. The lapse of a monopoly does not usually mean this, any more than the lapse of a patent means the compulsory winding up of the patentee. Except for a long concession of exclusive rights the cables to France would never perhaps have been laid. That the monopoly is doomed seems to us an international necessity; but that the company is doomed as well is a circumstance wholly exceptional; and this fact entitles the shareholders to more liberal treatment than public opinion at present seems disposed to afford.

The London Electric Supply Corporation (*née* "The Sir Coutts Lindsay Electric Lighting Company") are at length showing signs of abandoning the reserve with which (for easily understood and very proper reasons) they have hitherto conducted their operations. As may be seen in another column, they even go so far as to speak openly of their projected station at Deptford, where within twelve months they hope to have a 200,000 light plant installed. This company have our heartiest wishes for the success of their enterprise, and we trust that nothing will arise to check the rapid progress which they are anticipating.

The subject of working transformers in series connection has not, since the early failures, received the attention which it deserves, and we are glad that Mr. Bernstein has taken occasion to bring the question before the Society of Telegraph-Engineers and Electricians. It is quite probable that in the adjourned discussion which will have taken place before these lines meet our readers something more may have transpired upon this subject, but, meanwhile, we may offer one or two remarks upon some points which we do not remember to have seen elsewhere referred to. In addition to the advantages of this method of working, which are common to all constant-current systems, there is also an important element of safety which distinguishes the series from the parallel transformer. If we short-circuit the secondary coil of a transformer joined in parallel upon the mains, we get a tremendous rush of current through the primary. Of course, in practice, we assume that no harm would be done, because the fuse in the secondary circuit would immediately melt; and even if this fuse hung fire the primary coil would still be protected by its own fuse. But while this is perfectly true we ought, perhaps, to recognise more fully than is usually done that the fusible wire is a drastic remedy, for which electric lighting has at times to pay for heavily by the trouble and annoyance which its action

Digitized by Google

occasions. In fact, we quite agree with Mr. PREECE, who, on another page, speaks of fusible cut-outs as "effective, but somewhat barbarous." Now, with a series transformer an accidental short-circuiting of the secondary is, of course, unable to increase the current in the primary, and, in fact, owing to the enormous lag occasioned, it need not necessarily increase the output of the secondary at all. We should hardly like at the present moment to say that fuses may be alogether dispensed with on such a circuit, but it is certain that their use may be very much restricted without in any way decreasing the safety of the installation.

IN Mr. KAPP's paper the question of series transformers is, however, briefly dismissed with a remark to the effect that in such a case a movable core is obviously necessary to regulate the secondary terminal potential—which, of course, is tantamount to saying that the thing is impracticable. But we venture to think that the above statement is not entirely obvious. It is, for instance, *possible*—though certainly not advisable—to obtain regulation for a series transformer without undue loss of energy by means of an automatic regulating mechanism. A very ingenious device of this description was made some time ago by Mr. F. H. NALDER. Mr. A. WRIGHT, of Brighton, has, we believe, done much the same thing, but it is, of course, fully recognised, even by the inventors themselves, that regulation by automatic mechanism, even though the core is untouched, is inadmissible as a practical device. Next there is the plan of compound winding, as proposed by Profs. AYRTON and PERRY, of which a diagram will be found on another page. But the practicability of this arrangement is hardly yet assured. After this we have the "impedance" coils of Messrs. SHARP and KENT, which were referred to in Mr. MACKENZIE's paper. A full description may also be found in *The Electrician*, April 29, 1887. This device seems to fulfil its purpose quite satisfactorily, and though we believe that from theoretical considerations it has been shown that its action is necessarily limited in range, yet in practice we understand that no such limit is apparent. These are points on which we should be glad of further information. Once more, if we adopt the view which some people hold (Mr. BERNSTEIN amongst others), that a house may be cheaply and conveniently wired by taking a separate pair of leads to each lamp from a common switch-board (where all the fuses would be placed), then we may, if we like, have a separate secondary coil for every lamp, subdividing the cores to the same extent. This arrangement will evidently be perfectly self-regulating with a constant primary current, but it is also evident that it involves a somewhat more costly transformer, neither is it applicable for large sub-station transformers, such as Mr. KAPP advocates. Lastly, it may be shown that a series transformer would be perfectly self-regulating if there were no self-induction in the secondary coil. We cannot, of course, do away with the coefficient of self-induction without, at the same time, cancelling the mutual induction; but, as Mr. SUMPNER has shown, it is theoretically possible to compensate self-induction by the addition of capacity. If, therefore, we had a condenser of suitable dimensions joined as a shunt across the terminals of the secondary we ought, apparently, to get self-regulation. It may be that the successful series transformer system has yet to be devised, but we feel tolerably sure that the advantages enumerated by Mr. BERNSTEIN (whose speech will be found in another page), together with those above mentioned, are amply sufficient to make the question worthy of the attention of electrical engineers.

AN esteemed provincial contemporary, the *East Anglian Times*, is distinguished above all its compeers by a most laudable enthusiasm for the electric light. A few days since Messrs. PARIS and SCOTT, the well-known firm of electrical engineers at Norwich, invited the members of the Ipswich Scientific Society to visit their works, and this leads the representative of the above-named journal to write a really remarkable article on "The Making of Electric Light." The reporter first achieves distinction when he describes the building of an armature—"a curious cylinder," with "multitudinous iron discs," "numberless longitudinal grooves," and miles of copper wire. But this is nothing to his description of the machine at work:—"The "cylinder runs through the centre of the magnet, and "is set revolving. What then happens is almost beyond "description; but the magnets produce electrical currents "one way, and the cylinder, technically called the armature, "makes them in another direction. The rival currents, as it "were, fight and foster one another, increasing and developing "by the friction and competition. The cylinder wins the day, "catches hold of the electricity, and carries it away into won-"derfully built-up contrivances of copper and mica, called com-"mutators. These revolve with the cylinder at a terrific speed, "and give off the electricity into threads of copper bound "together, technically called a brush. From the brush the "electricity runs into the wire, and thence to the lamp."

THE incandescent lamps of high candle-power which can now be obtained both from the Edison-Swan Company and from Messrs. Clarke, Chapman, Parsons and Co., are rapidly coming into extended use. At the Forth Bridge Works they have almost entirely replaced the Lucigen light, and they are also largely used for indoor lighting in the workshops. In some of the earlier specimens of these lamps which came under our observation the glass blackened very quickly, but this defect appears now to have been almost entirely overcome. There can be very little doubt that these lamps will take a very important place indeed in the future of electric lighting.

The Barcelona Exhibition.—The 28th inst. is the latest date at which applications will be received for space at this Exhibition.

Sofia, Bulgaria.—The Municipal Council of this city have offered a premium of 5,000fr. for the best scheme for lighting the town, either by gas or electricity.

The Khotinsky Lamp.—The Khotinsky incandescent lamp is rapidly coming into use in France. These lamps are made at Rotterdam, and the process of manufacture is kept strictly secret.

Tenders Asked For.—We would direct attention to an announcement which will be found in another column to the effect that the Council of the City of Wellington, New Zealand, are open to receive tenders for lighting that city by electricity.

Digitized by Google

Kensington.—The sub-committee of the Kensington Vestry have advised the works committee of that body to postpone a decision on the order sought by the Kensington Court Electric Light Company, in order to give rival companies time to present their plans.

Shop Lighting.—The grocery and other departments of Messrs. Crisp and Co., Seven Sisters-road, N., are being fitted with the electric light by the Maxim-Weston Electric Company. This company has now successfully lighted the premises of several well-known firms in the grocery and provision trades.

Spanish Tender for Telephone Service.—The *Madrid Gazette* of February 14th contains a Royal Order authorising an invitation for tenders for the establishment and working of a telephone service in Felanitx (Balearic Isles), subject to the conditions published in the official journal of 15th June, 1886. Tenders are to be adjudicated upon on March 17th next.

The Mexican Telegraph Lines and the Western Union.—We recently referred to rumours current in Mexico that the Western Union were contemplating the acquisition by purchase of telegraph lines in Mexico. Advices just received from the City of Mexico now report that Mr. Thos. J. Eckert, general manager of the Western Union, has telegraphed denying the rumour.

Spanish-Balearic Cable.—With reference to the submarine cable between Spain and the Balearic Isles, which is reported to have been interrupted for some time past, we learn from *Industrias é Invenciones* that the Spanish Government contemplates the laying of a new cable. It is expected that the work, if definitely decided upon, will be given to a foreign company.

The Electric Lighting Act.—In the House of Commons Mr. Barclay has given notice that he will ask the President of the Board of Trade in how many cases the powers obtained by Provisional Orders under the Electric Lighting Act of 1882 have been actually exercised; why so little progress has been made with electric lighting under the Act of 1882; and whether the Government intends to amend the Act, with the view of encouraging the development of electric lighting.

Lighting of the Royalty Theatre, Glasgow.—Mr. Geipel writes as follows:—"In your last issue you state that the above theatre has been supplied with a complete installation of electric light apparatus by me. May I ask you to correct this by stating that the contractors for the supply and maintenance of the installation are the Anglo-American Brush Electric Light Corporation, my employers, on whose behalf I made the arrangements and supervised the work?"

The Electro-Harmonic Society.—This society will give its first amateur concert at St. James's Hall on Friday, March 2. This will be a "ladies' night," and we understand that it is proposed to take off the stiffness of an ordinary concert by seating the audience, as at the smoking concerts, the chairs being grouped around small tables. This innovation will, we are sure, meet with the approval of the members of the society. We trust that it will also meet with the approval of their lady friends.

Method of Saving Horses from Fires.—A New York man has invented a device to save horses in case of fire. It can be worked either by electricity or by hand. At a certain temperature a bell will ring, and the moment the bell shall ring the doors will fly open, the horses will be unhitched, and two small streams of water will strike each horse in the face. To escape the water the horses will back out of the stalls, and, once out of them, they will have an opportunity of seeing a way of escape through the open doors.

Electric Light at Marlborough House.—His Royal Highness the Prince of Wales has decided to have the State apartments and principal rooms in Marlborough House lighted by electricity, and it is expected that all the necessary apparatus will be fixed in time for the silver wedding celebration early next month. The work is in the hands of the officials of the Prince's household, who are assisted by a special staff directed by Mr. T. O. Belshaw and the Court electrician, Mr. W. H. Massey. The current will be supplied by the Sir Coutts Lindsay Company from the Grosvenor Gallery Station.

The Electric Lighting of Ships.—The new cruiser "Chicago" is now being fitted out for service at the Brooklyn Navy Yard. The electric plant is already installed, and consists of two Edison compound dynamos, each for 350 lights, driven by Armington-Sims engines. Lead-covered cables have been used throughout the ship, the total length of circuits being about 40,000ft. The cables are laid in wood casing, and Edison watertight cut-outs are fitted to every lamp, and all the switches employed are also watertight. The total insulation of the circuits is said to be about 100,000 ohms.

Electric Fire Alarms at Bristol.—At the request of Sir William King the Western Counties and South Wales Telephone Company have erected fire alarm posts at Kingston Cross and Palmerston-road, Bristol. These posts are connected with the chief police and fire station at Landport. The system is the same as that adopted by the Metropolitan Fire Brigade. The Western Counties and South Wales Telephone Company have provided this system as an experiment, and will maintain it free of cost to the borough for three months, by which time the Corporation will have been able to form an opinion whether they desire to adopt it or otherwise.

Long-Range Lighting.—As one of the most marked instances of the advantages of transformers in electrical distribution, we note, says the New York *Electrical Review*, a new station under the Westinghouse system at Edgewood, a suburb of Pittsburgh, now in successful operation. The circuit is in all eight miles long, and the distance from generators to point of distribution four miles. A No. 4 wire is used for the line, and at present there are about 500 lights in use at the distant point, but wiring goes forward as rapidly as possible for nearly 5,000 more lights. This will be, when finished, the most important illustration of long-distance distribution yet attempted, and, so far, not a hitch has occurred.

Hastings.—A long discussion took place at the Town Council meeting on Friday last in reference to the recommendation of the committee to the effect that a resolution formerly passed, refusing permission to the Electric Light Company to put up overhead wires in several streets, should be rescinded, and that the committee be empowered, if they saw fit, to grant the application upon such terms and conditions as might be agreed on. The recommendation was eventually carried. The local paper says:—"We feel that the council have acted rightly and wisely, for besides doing justice to a company which is entitled to look for consideration at their hands, they have averted what might have proved to the town a troublesome law suit."

Cable Companies: Football Victory.—A correspondent writes from Porthcurno:—"Dear Sir: A return football match was played against Penzance on the 11th, and again resulted in a victory for the United Cables by 3 to 1. Saunders kicked the goal for Penzance first half-time. During the second half the good passing of the Cable forwards won for them the game, Evans shooting the first and Raymond

Digitized by Google

the last two goals. Team: Martin, goal; Leahy and Palmer, backs; Ernest Ash, Davies, J. B. Sweeting, half-backs; Adson, W. H. Raymond, centres; Derrick M'Lean, left wing; Walton Evans, right wing; umpire, Mr. Thorngate. Messrs. Adson and Walton represented the Western Union Cable Company, the rest Easterns or Exiles."

The Submarine Telegraph Company.—In the House of Commons, on Saturday last, in reply to questions from Sir G. Campbell and Mr. Henniker Heaton, Mr. Raikes said:—"The Submarine Telegraph Company have been informed that it is not the intention of Her Majesty's Government to agree to any renewal of the concession to them which will expire shortly. No agreement has been come to with the company as to the purchase of their plant and transfer of their undertaking; and I do not think it would be to the public interest that any statement as to the details of negotiations should be made until some definite decision shall have been arrived at. I may say, however, that the inferences suggested by the question of the hon. member for Canterbury are very inaccurate."

Messrs. E. Stanford's Parliamentary Map of the Metropolitan District.—This year's issue of the "Map of the new Railways, Tramways, and Miscellaneous Improvements for the Metropolitan District," deposited in the Private Bill Office at the commencement of the present Parliamentary session, shows by a red border the district which is sought to be covered for electric lighting purposes by the South Metropolitan Electric Lighting Company. This district is bounded as follows:—Commencing at Piccadilly, by Shaftesbury-avenue, Endell-street, Great Queen-street, Lincoln's Inn-fields, Chancery-lane, Fleet-street, New Bridge-street, Victoria Embankment, Waterloo Bridge and Road, Lower Marsh, Westminster Bridge-road, Palace-yard, Great College-street, Victoria-street, James-street, Buckingham Palace, and the Green Park.

Water-Soaked Dynamos Dried by Steam.—A few weeks ago, says the *Western Electrician*, the station of the Brush Company at St. Louis was badly damaged by fire. When the fire department left the place the dynamos were standing deep in water. Notwithstanding the difficulties in the way, the most active and energetic measures were taken to get the station in running order again. The water was drained away and then a steam radiator was placed either side of each dynamo and a tarpaulin thrown over the top, making as it were an oven for each machine. Steam was then turned on and for sixteen hours the dynamos were subjected to the heat. At the end of that time the dynamos were found to be thoroughly dried out and in condition to use again. Seven of the dynamos were found to be in perfect order and only one was found to be slightly damaged.

The Schanschieff Battery.—Her Royal Highness Princess Christian has accepted from the directors of the Schanschieff Battery Syndicate a portable electric reading lamp fitted with the Schanschieff battery. The lamp is a very handsome one, and is enclosed in a rosewood case inlaid with ivory, by Cooper and Holt. Mr. Schanschieff having explained the invention and shown the interior, the Princess expressed herself as greatly pleased at the simplicity of charging, the absence of wires, its absolute freedom from gas, smell, or risk of accident, and, in particular, with the ratchet arrangement by which the light was regulated from 1 to 10 candle-power, or totally extinguished and relighted at will. Mr. Schanschieff then exhibited one of the reversible automatic miners' lamps, in which her Royal Highness expressed much interest.

The National Telephone Company's System in Scotland.—We have received from Mr. A. R. Bennett, of the National Telephone Company, a map of central Scotland, showing the existing and projected trunk lines. The existing system extends from Forfar in the north to Ayr in the south, and east and west from Greenock to Dalkeith, and includes all the important places without exception in this extensive tract. The following are the chief lines which it is at present intended to carry out:—From Kirkcaldy along the coast line to St. Andrews; an extension eastwards from Edinburgh to Dunbar, and southwards to Galashiels and Selkirk; the opening of a second route between Edinburgh and Glasgow *viâ* Bathgate and Coatbridge; and a line from Alloa to Perth *viâ* Kinson and Newburgh. In addition to these places named these lines will serve many smaller towns and villages *en route*.

The West Metropolitan Tramway Company and Electrical Traction.—At the meeting of shareholders in the West Metropolitan Tramways Company, held on the 17th inst., the chairman (Mr. E. H. Bayley) denied a statement made in a circular issued by a shareholder named Willis that the directors had been spending money on electrical experiments. What they had done was to carry out an undertaking which they gave to the shareholders at the general meeting eighteen months ago that they would make an application to Parliament and the local authorities for permission to make use of electricity as a motive power in case it should be found advantageous for the company to do so. They had made that application, and in spite of the most tremendous opposition they had succeeded in getting the authority. If they could adopt electricity that would enable them to deal successfully with the railway competition, and to reduce considerably the working expenses.

The "Corner" in Copper.—In the French Chamber on Saturday last there occurred a scene which has often its counterpart in the British House of Commons, where inconvenient questioning is the rule and evasive answering hardly less so. M. Laur wanted to know whether the alleged combination of a French syndicate to raise the price of copper did not come under the penal provisions of Article 419. The Minister of Justice replied at some length that the combination was not proved; that copper had been going down lately, and that both rise and fall might be due to economic causes; but that it must not be supposed that Article 419 was dead because it was seldom applied; and if it were found that an unlawful combination existed to secure a monopoly of any article of merchandise "there are tribunals in France competent to apply the penal code." Then, of course, the subject dropped.

Telephones at Ventnor.—The Equitable Telephone Association has now completed telephonic communication between the ten different blocks of the National Hospital for Consumption, Ventnor, Isle of Wight. Eleven of the A type Swinton telephones are employed, and all are connected to a central exchange switch-board in the head nurse's room, so that communication between any one block of the hospital and any other can be easily effected. The wires are led along an underground passage, which connects all the blocks together. As the hospital extends over a considerable distance, and the several blocks are detached from one another, it is expected that telephones will prove a great convenience to the resident staff, and the switch-board has been arranged so as to admit of the residences of some of the medical officers living away from the hospital being connected, should this be considered advisable at some future time.

The Lancashire and Cheshire Telephone Company.—The new issue of the "Telephone Directory" of the Lancashire and Cheshire Telephone Company is a bulky volume of

Digitized by Google

393 pp. (including advertisements). In addition to the long lists of subscribers, members in the towns and villages of Lancashire and Cheshire, much interesting information can be obtained from this volume as to the extension of the telephone system in the North. A map showing the existing and proposed system of trunk wires is included. From this map it will be seen that the district served by the company is already almost completely covered with a network of trunk wires, and, with one exception, the extensions in progress are of an unimportant character. The exception referred to is a line northwards from Blackburn, which will bring Lancaster, Ulverstone, and Barrow into the company's system. In turning over the pages of this book, it is difficult to realise that the first exchange was opened in this district little more than eight years ago.

Personal.—Mr. A. E. Kennelly (late of the Eastern Telegraph Company) is now delivering a course of evening lectures to the whole of the staff engaged at Edison's new laboratory. The lectures are spoken of very highly by the local press.—We regret to learn that M. Cornélius Herz, the editor of *La Lumière Electrique*, has left his native land, and that his speedy return is scarcely to be anticipated. According to the *Bulletin des Sociétés d'Electricité*, his departure is owing to the non-success of certain financial operations in which he had been interested. It is, however, much to be hoped that this unfortunate incident will not be allowed to have any prejudicial effect upon the valuable journal which M. Herz has edited for many years with so much ability and success.—We have to record with the most sincere regret that M. Lucien Gaulard, whose name is so closely associated with the introduction of the system of distribution by alternating currents, is suffering from mental derangement. We trust, however, to hear of his speedy and complete recovery.

The Lighting of the Temple.—Mr. Francis Teague, of Stanhope-street, Euston-road, writes us as follows:—"In your issue of the 10th I notice a slight error in your Note referring to the electric lighting at the Temple, viz., that the church had been fitted temporarily only. The church possesses a permanent installation, which was put in during December, 1886, and January, 1887. After several experiments had been tried in order to determine the most suitable arrangement for the lamps, they are placed so as to be as little conspicuous as possible; in fact, they are not noticeable when not burning, for throughout the edifice they are fixed so as to project slightly beyond the tops of the capitals of the columns supporting the magnificent vaulted roof. By this plan they in no way interfere with the general character of the architecture, which is a most desirable feature in installations of this order; and, I may add, that the installation has been in regular use since its completion. The contractors were Messrs. Mortimer, Shepherd and Co., of 2, Great Queen-street, W.C., but their existence as a firm ceased in August, 1887, when they dissolved partnership."

A Remarkable Exhibition of St. Elmo's Fire.—"A remarkable exhibition of St. Elmo's fire" (says a correspondent of the New York *Electrical Review*) "was recently witnessed by the writer on the summit of the Sonnblick mountain in Austria, about 10,000ft. above sea level. The synoptic weather chart for September 9 shows that there was at the time a ridge of high pressure over Central Europe, with light and variable winds at the low level stations. On the Sonnblick it had rained all day, with a south-west to a southerly gale. The pressure, which was high (nearly 20·7in., the normal being about 20·3in.), was falling irregularly, and the temperature was about 37deg. F. About 6 p.m., with a sudden shift of the wind to the north, the pressure rose and the temperature fell to 30deg. F., causing the rain to change to sleet and snow. About this time brushes of violet light were noticed outside the observatory upon the points of the lightning rod, the anemometer cups, and even upon projecting pieces of rock. From the heads of the observers and from their outstretched hands similar brushes of light streamed (resembling the positive discharge from an electric machine), accompanied by a cracking noise and a pricking sensation. This continued until the wind, which meantime had fallen to a calm, changed its direction to south-west and the pressure became stationary. The temperature soon rose above the freezing point, but the snow continued to fall for some hours."

The German Government and the Telegraphs.—The Berlin correspondent of *The Times* states that the German Reichstag has read twice the Bill for confirming the agreement for the purchase by the Government of the cables of the German Union Telegraph Company, and the third reading may be expected very shortly. By this measure the Imperial Post Office will from the 1st January, 1889, or the 1st of July, 1888, if it so desire, have possession of a four-wire cable from Emden to Lowestoft, and a cable from Greetsiel to Valentia (Ireland) now being used for German-American telegrams in connection at Valentia with the Anglo-American cables. The company was established in Berlin in 1871, but the capital, which was found in England, is now held chiefly by the Globe Telegraph Company and the German Union Telegraph and Trust Company, of London. The total capital of the company is 6,600,000m., and the purchase money to be paid by the Government is 6,300,000m.; but the company retains its reserve fund. This seems a good bargain for the German Government; but in view of its determination to work the telegraphic service between the two countries and materially to reduce the tariff, it was seen to be impossible to refuse the terms proposed by Dr. von Stephan. The Government takes over the agreements with the Anglo-American Company for the working of the American traffic Sir James Anderson is now in Berlin.

Chess by Telephone.—A match took place at Stirling on Saturday between the Glasgow Chess Club and the Counties of Perth and Forfar. One of the players being unable to leave Dundee this game was played by telephone. A correspondent gives the following details:—The National Telephone Company, Limited, fitted up the necessary wires and apparatus to the Douglas Hotel from their Stirling Exchange, and placed the trunk wire between Dundee and Stirling at the disposal of the players. Mr. Sandeman arranged to play in a residence in the west end of Dundee already connected to the Dundee Exchange. The local instruments were connected to each end of the trunk wire between the two towns, and thus the players were put in direct telephonic communication. The game was a very close one, and concluded, on time being announced at 6:30 p.m., by Mr. Sandeman resigning. The distance spoken over *viâ* the cable under the Tay and through Fifeshire was nearly 72 miles, but the announcement of the moves was as clear as if the speakers had been in the same town. At the conclusion of the match Stirling telephoned the victory of the Counties to Dundee, the Counties having 15½ games to 14½ for Glasgow. Messages were then telephoned to and from Mr. Sandeman and various friends at Stirling. The game by telephone was conducted most satisfactorily, and opens up a new departure in facilitating the playing of games and matches with friends or clubs at a distance. Mr. John D. Miller, the district manager for the company, and others interested in the game were present.

NOTES ON ALTERNATE CURRENTS.

BY J. A. FLEMING, M.A., D.SC.

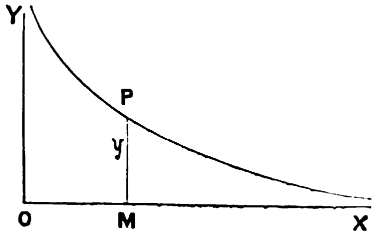
(Continued from page 316.)

A curve such that the rate of growth or shrinkage of the ordinate is proportional to the ordinate itself is called a logarithmic curve.

Let a curve (Fig. 20) be described by the extremity P of an ordinate, P M, which moves uniformly along O X, parallel to itself, and let P M *shrink* in height at a rate proportional to its height at any instant. Then the equation to such a curve is

$$y = -A\frac{dy}{dt},$$

and since e^{-Bx} (where e = the base of Naperian logarithms $= 2{\cdot}71828$) is a function which fulfils this condition of having



a differential coefficient proportional to itself, we can write the solution of the above

$$y = e^{-\frac{t}{A}},$$

for it is at once seen that by differentiating the equation

$$y = e^{-\frac{t}{A}}$$

we obtain $$\frac{dy}{dt} = -\frac{e^{-\frac{t}{A}}}{A};$$

and therefore $$y = -A\frac{dy}{dt}.$$

Returning to our equation for the current we can write as an equivalent for the equation

$$I - i = T\frac{di}{dt}$$

the equation $$I - i = -T\frac{d(I-i)}{dt},$$

or $$\frac{dt}{T} = -\frac{d(I-i)}{I-i};$$

intergrating this we have as a solution

$$-\frac{t}{T} = .\log(I-i) + \text{const.}$$

The constant has to be determined by the condition that when $t = 0$ $i = 0$, which gives const. $= -\log$ I. Hence the complete solution is

$$-\frac{t}{T} = \log(I-i) - \log I,$$

or $$I - i = Ie^{-\frac{t}{T}}.$$

This last equation expresses the fact that the amount by which the current falls short of its full value I, at any time t, after applying the E.M.F., is a fraction of its full value, equal to $e^{-\frac{t}{T}}$. When $t = 0$, or at the instant of closing circuit $I - i = I$, or the current $i = 0$, when $t = T$, $I - i = \frac{I}{e}$, or the deficit from full current is equal to $\frac{1}{2{\cdot}718}$ × the maximum current. Hence we may define the *time constant* of a circuit as the time reckoned from the instant of closing the circuit in which the current rises up to a value equal to $\frac{e-1}{e}$ of its full value, or to about ·632 of its maximum value. Approximately we may define the time constant as the time from closing the circuit in which the current rises up to ⅔rds of its maximum value $\frac{E}{R}$.

The rise of current strength in a wire of inductance L and resistance R when a steady external electromotive force, E, is applied to the circuit can be represented by a current curve, as shown in Fig. 21.

Let O X (Fig. 21) be a time line on which we mark off time as lengths reckoned from O. Let lines drawn vertically to this represent the current strength at any instant in a circuit of time constant T, inductance L, and resistance R, and let $OY = I = \frac{E}{R}$ represent the maximum current which is finally found in the circuit. On applying the electromotive force E to the circuit, the current strength grows up in the wire as graphically represented by the curve, the law of growth being that the rate of growth at any instant, multiplied by the time constant, is equal to the difference between the actual current at that instant and the maximum current strength finally attained, or symbolically

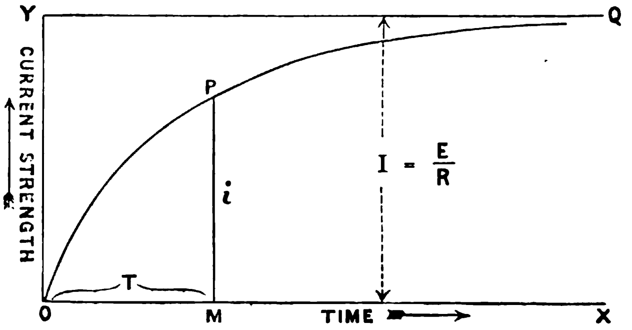
$$I - i = T\frac{di}{dt},$$

the solution of the differential equation being

$$I - i = Ie^{-\frac{t}{T}}$$

or $$i = I\left(1 - e^{-\frac{t}{T}}\right)$$

This last equation gives us the value of the current strength at any time t seconds after closing the circuit in terms of the time constant and the maximum current I which is finally attained.



The maximum current I would be produced at once in the circuit if its inductance were zero, so that we may finally formulate the law of growth of current in a circuit of inductance L, resistance R, and no sensible capacity, by saying that *the current strength at any instant added to the rate of growth of the current strength at that instant multiplied by the time constant, is equal to the current which would exist in the circuit if inductance were zero.*

The application of this principle to the case of simple periodic currents will lead to another proposition. Let there be a circuit which has an inductance L and resistance R, and let a simple periodic electromotive force act upon it. Let the maximum value of this E.M.F. be E, and let p stand for $2\pi n$ when n is the frequency of the oscillations, or $n = \frac{1}{T}$ when T is the duration of one single complete period; p is a quantity of the nature of an angular velocity, and may be called the *pulsation*. Then if t is the time which has elapsed from the commencement of the wave of E.M.F., and e is the actual value of the E.M.F. at that instant,

$$e = E\sin pt.$$

In this case the impressed electromotive force varies from instant to instant, passing from zero to a maximum, E, then to zero again, and then to a negative maximum − E. Accordingly our fundamental equation for the current strength at any instant is expressed thus,

$$\frac{d(Li)}{dt} + Ri = e = E\sin pt.$$

Digitized by Google

For, the total rate of expenditure of work on the circuit at any instant when the current has a value i is $e\,i$, and this must be equal to the rate at which electrical work is being dissipated as heat, which is $R i^2$ by Joule's law, and the rate at which work is being stored up in the magnetic field, which is $\frac{d}{dt}(\frac{1}{2} L i^2)$;

hence, $$\frac{d}{dt}(\tfrac{1}{2} L i^2) + R i^2 = e\,i,$$

or, $$L \frac{di}{dt} + R i = E \sin p\,t.$$

In order to solve this differential equation and obtain the value of the current i in the circuit at any instant under the periodic electromotive force, we may adopt a well-known algebraic device, and substitute for the value of $\sin p t$ its equivalent in exponential terms. It is shown in treatises on trigonometry that

$$\sin \theta = \frac{e^{k\theta} - e^{-k\theta}}{2k},$$

where $k = \sqrt{-1}$, and e is the number 2·71828, which is the base of the Naperian logarithms.

Also $$\cos \theta = \frac{e^{k\theta} + e^{-k\theta}}{2};$$

hence $\cos \theta + k \sin \theta = e^{k\theta}$.

These are called the exponential values of the sine and cosine.

Taking the equation

$$L \frac{di}{dt} + R i = E \sin p\,t,$$

we divide both sides by L and writing T as before for the *time constant* $\frac{L}{R}$, we get

$$\frac{di}{dt} + \frac{i}{T} = \frac{E}{RT} \sin p\,t.$$

Multiply both sides by $e^{\frac{t}{T}}$ (e being the exponential base, not impressed E.M.F.), and we have

$$\frac{di}{dt} \cdot e^{\frac{t}{T}} + \frac{i}{T} e^{\frac{t}{T}} = \frac{E}{RT} e^{\frac{t}{T}} \sin p\,t.$$

The left hand side of this equation is the complete differential of $i e^{\frac{t}{T}}$, and may be written $\frac{d}{dt}\left(i e^{\frac{t}{T}}\right)$, and on substituting the exponential value for $\sin p\,t$ and putting k for $\sqrt{-1}$, we have

$$\frac{d}{dt}\left(i e^{\frac{t}{T}}\right) = \frac{E}{2kRT}\left\{ e^{\left(\frac{t}{T} + kpt\right)} - e^{\left(\frac{t}{T} - kpt\right)} \right\}$$

The right hand side of this last equation is the complete integral of

$$\frac{E}{2kRT}\left\{ \frac{e^{\left(\frac{1+kpT}{T}\right)t}}{\frac{1+kpT}{T}} - \frac{e^{\left(\frac{-kpT}{T}\right)t}}{\frac{1-kpT}{T}} \right\}$$

which becomes by simplification

$$\frac{E}{2kR} e^{\frac{t}{T}} \left\{ \frac{e^{kpt}}{1+kpT} - \frac{e^{-kpt}}{1-kpT} \right\}$$

hence equating both sides when integrated we have

$$i = \frac{E}{2Rk}\left\{ \frac{e^{kpt}}{1+kpT} - \frac{e^{-kpt}}{1-kpT} \right\}$$

Substituting back into sine and cosine terms, and recollecting that

$$e^{kpt} = \cos p\,t + k \sin p\,t,$$

and $$e^{-kpt} = \cos p\,t - k \sin p\,t,$$

we get finally

$$i = \frac{E}{R}\left\{ \frac{\sin p\,t - p\,T \cos p\,t}{1 + p^2 T^2} \right\}$$

If $p = 0$—that is, if the pulse is infinitely long, or the electromotive force continuous—then we have simply $i = \frac{E}{R}$, which is Ohm's law; but when p is not zero, and we have periodic variation of E.M.F., we see that the current value is not obtained by dividing E by R, but by multiplying this quotent by a factor. We can, however, put the above equation in a more intelligible form. Replace T by $\frac{L}{R}$, and let θ be an angle whose tangent is $\frac{Lp}{R}$;

hence $$\tan \theta = \frac{Lp}{R} = p\,T.$$

It follows by an easy transformation that

$$\cos \theta = \frac{R}{\sqrt{R^2 + p^2 L^2}}, \text{ and } \sin \theta = \frac{Lp}{\sqrt{R^2 + p^2 L^2}}.$$

We have then for the value of the current

$$i = \frac{E}{R}\left\{ \frac{\sin p\,t - p\,T \cos p\,t}{1 + p^2 T^2} \right\}$$

or, by substitution,

$$i = \frac{E}{\sqrt{R^2 + p^2 L^2}}\left\{ \sin p\,t \cos \theta - \sin \theta \cos p\,t \right\}$$

$$\therefore i = \frac{E}{\sqrt{R^2 + p^2 L^2}} \sin (p\,t - \theta).$$

This is the final solution of the equation

$$L \frac{di}{dt} + R i = E \sin p\,t = e,$$

and it shows us three things. First, that the phase of the current i is retarded behind that of the impressed electromotive force by an angle θ—such that $\tan \theta = p\,T = \frac{Lp}{R}$; and second, that the maximum value of the current is obtained by dividing the maximum value of the electromotive force by a quantity equal to $\sqrt{R^2 + p^2 L^2}$; and third, that the current curve is a simple periodic curve. The quantity $\sqrt{R^2 + p^2 L^2}$ is called the impedance of the circuit.

We have seen from the explanations on previous pages that the average or true mean value of a simple periodic quantity is equal to its maximum value multiplied by $\frac{2}{\pi}$. Hence, if we write Im for Impedance, we can put the equation, giving the value of the current produced by a simple periodic impressed electromotive force of maximum value E, operating on a circuit of resistance R, inductance L, with a pulsation p, in the form

$$i = \frac{E}{Im} \sin (p\,t - \theta),$$

and in words

	average current strength	=	*average impressed electromotive force* / *impedance*
and	maximum current strength	=	*maximum impressed electromotive force* / *impedance*

We see, then, that in the case of simple periodic electromotive force the quantity called the impedance appears to be related to the impressed E.M.F., just as does the resistance to the steady E.M.F. in the case of continuous currents, and the above may be called the equivalent of Ohm's law for alternate currents. Compare as below

For steady or continuous currents	current strength	=	*electromotive force* / *resistance*	(Ohm's law).
For simple periodic or alternate currents	average current strength	=	*average impressed electromotive force* / *impedance*.	

Digitized by Google

Instead of *average*, we may write in the above *maximum*, or *square root of mean square* of the current.

Impedance is a quantity which is measured like resistance, in ohms, and has for that reason been sometimes called the *virtual resistance.*

(*To be continued.*)

EXPERIMENTS ON THE CONDITIONS WHICH DETERMINE THE STABILITY OF A TELEGRAPH WIRE.

BY FRANK CAWS.

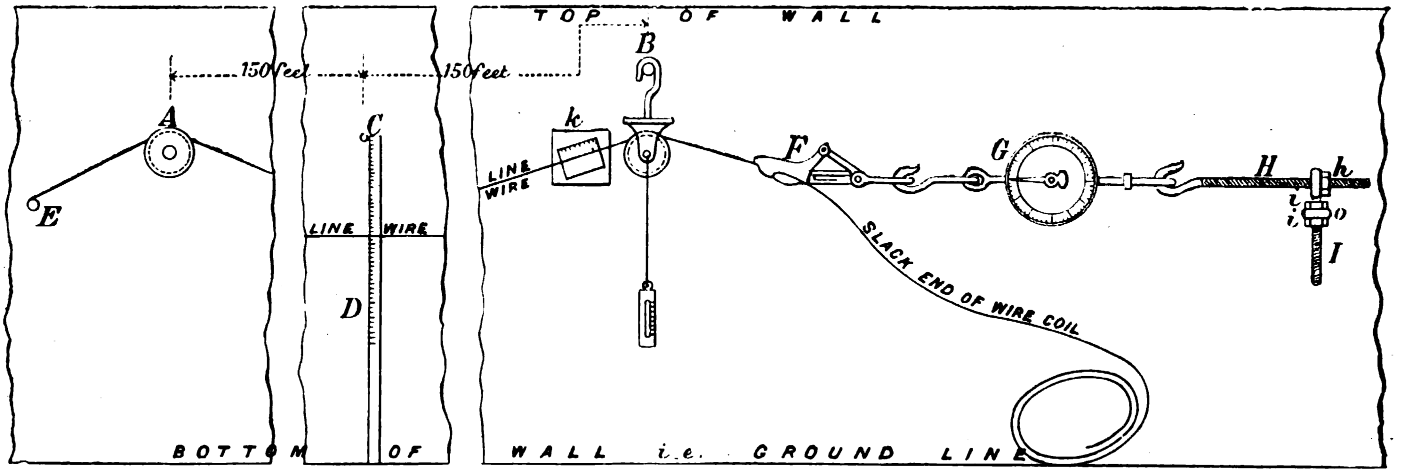
Part II.

While believing that engineers will find the diagram* given last week and other diagrams framed on a similar graphic system very handy for reference, I also append a table showing in figures the experimental dips under column E, dips given by the 14,500,000lb. modulus under column C, dips given by the 17,000,000lb. modulus under column C_1, and dips given by Mr. Preece's table under column P, likewise experimental stresses under column *e*, stresses given by the 14,500,000lb. modulus under column *c*, stresses given by the 17,000,000lb. modulus under column c_1, and stresses given by Mr. Preece's table under column *p*. And I add, with view to make the table complete for the use of students, experimental catenary lengths, and (which are practically the same) catenary lengths calculated by the 17,000,000lb. modulus under column L, catenary lengths due to 14,500,000lb. modulus under column *l*, and catenary lengths due to Mr. Preece's dips and stresses of inelastic wire under column marked (*). And to this I have added two columns for stretch, viz, column S for stretch as per 17,000,000lb. modulus, which corresponds very nearly with experimental results; and column *s* for stretch as per 14,500,000lb. modulus. Also I give for normal length of unstretched wire a column, marked N, for 17,000,000lb. modulus (agreeing very nearly with experiment); and another column, *n*, for the 14,500,000lb. modulus; and still another column, *o*, which results, of necessity, from Mr. Preece's table. All these particulars are, of course, not needed by the practitioner so much as by the student who desires to understand "the conditions that determine the stability of a telegraph wire." The practitioner will find all he needs under columns E and *e*, and likewise per lines E and *e* of the diagram.

The difference between the experimental stress, 81·75lb., and the calculated stress, 82·5lb., is traceable to the difference between the catenary and parabola. In point of fact, the real difference due to neglect of catenary must have been about $\frac{0·78}{82·5}$ instead of $\frac{0·75}{82·5}$, for at the conclusion of the experiments I cut the wire exactly at the two points of support; and, weighing it, discovered that instead of weighing 5·68lb. (the weight due to a 100lb. per mile wire) it actually weighed 5·9lb. The experiments on which the above table is based were repeated on two occasions with the same results. The copper wire was on these two occasions of the same quality as the Government wires, and was quite new. I also tried the same experiments with a copper wire which had been about a year and a-half in use on a telephone company's span in this district, and which (after the experiment) was cut and weighed, making 5·85lb. The differences between corresponding dips and stresses of new and old wires proved to be as follow: — *new*, dip 2·98ft., stress 70·33lb.; *old*, dip 2·96ft., stress 70·25lb.; *new*, dip 3·345ft., stress 63·25lb.; *old*, dip 3·36ft., stress 61·75lb.; *new*, dip 3·895ft., stress 57lb.; *old*, dip 3·79ft., stress 54·75lb. There was one spliced joint in the old wire catenary; but the new wire catenary was in one length without joint. Between each of the dips named the catenary was paid out 0·054ft., as hereinafter described.

It now remains for me, in conclusion, to explain in detail how the experiments were conducted.

I obtained permission to use a very long and perfectly straight wall near the railway station at Monkwearmouth;



and on this wall I marked, with the utmost accuracy, the two points of support of a 100-yard span, and an intermediate point at midspan, all three points on one level. After I had had steel pins fixed in the wall at the required levels and distances, I carefully remeasured the distances and verified the levels by means of my surveyor's level-staff and "dumpy." The following description refers to the diagram:—A is a steel pin driven into the wall, having threaded upon it a porcelain shackle bell. B is a steel pin driven into the wall, exactly 300ft. distant from A. C is a steel pin driven into the wall exactly midway between A and B. A plated pulley with grooved edge is suspended from B, and attached thereto is a thermometer suspended as a plummet. The top edge of this pulley is exactly level with the top of the pin C and with the top bed of groove of bell A. So, when the line-wire is suspended over pulley at B and bell A, the exact dip of the catenary can be measured down from C by the vertical rule D, which, being graduated in decimal parts of a foot, gives at once the figures in column E, per above table. At E (diagram) the line wire is securely fastened round a pin driven into the wall. At the opposite end of the span the line-wire is securely held by the linesman's vice, F, which is hooked on to the Salter's spring balance G; which, in turn, is hooked on to H, which is a screw-threaded bolt about 14in. long, threaded through an eye at the top end of the vertical bolt J, and having an adjusting nut, *h*, against the said eye of vertical bolt. The vertical bolt J is dropped through an eye formed

* In Part I., the diagram marked 5 should have been marked 6, and diagram marked 6 should have been marked 5.

on the outer end of a strong spike, *o*, driven into the wall; and, as J is screw-threaded and fitted with the two adjusting nuts *i i* above and below *o*, it is easy by using the nuts *i i* to raise or lower H to any exact height, so that the angle of the line-wire may be equal on both sides of pulley B, which is evidenced by the (thermometer) plummet hanging in the same vertical line with pulley axle and nail-head B. A piece of board, *k*, is nailed to the wall close to the pulley B; and to this board is affixed a card, carefully graduated along its upper edge into divisions of 0·003ft., each of which divisions is the measure of expansion the 300ft. span of copper wire will undergo for each degree F. Upon the line-wire, close to this card, a small, light, delicate pointer is fixed. Then, by working the screw nut *h*, the line-wire can be slacked or tightened, and the little pointer moving along the graduated edge of the card indicates with extreme nicety the measure of extension or contraction which the catenary arc has undergone. Throughout the experiments the thermometer was continually observed. On the occasion of the first experiments the thermometer varied from 49 to 50½deg. F., and allowance was carefully made (by means of the card) for this variation. But on the occasion of the second and last experiments the thermometer stood steadily at 40deg. F. throughout the whole time.

I took the Salter's spring balance G (which was a perfectly new one) to the Weights and Measures Office, Sunderland, and had it most carefully tested by the officials, and proved it quite correct before experimenting with it. On the first occasion there was no wind at all, and on the second occasion, thanks to the sheltering wall, the light breeze which was blowing did not interfere with our results. On both occasions I had the valued assistance of the engineer of one of our largest telephone companies, as well as of several members of his staff, and of my own pupils. A careful study of my apparatus, as above sketched and described, will convince the student that all possible error from friction was eliminated. The effect of expansion on dip and stress was produced and proved by first setting the line wire to datum dip of 2·5842ft., and then setting the pointer on line-wire to zero on the graduated card. Then, by means of screw nut *h*, slacking off, so as to let the pointer travel 0·054ft. along the card, we obtained the dip due to an increase of 18 deg. F. It is true that when the length of the catenary is expanded by actual heat no addition is made to the weight of wire in the span. And it is true that, by the experimental equivalent for expansion, the weight of barely ⅝in. length of wire (per 18 deg.) is added to the span; but that addition has no measurable consequence or effect. For all practical purposes the equivalent for expansion adopted throughout these experiments is a true equivalent, giving the same dips and stresses as the actual expansion would give. Thus, it will be understood that starting from a dip of 2 5842ft. (due to 22deg. F. at quarter breaking strength of wire) and adding, at each experiment, 0·054ft. to catenary, we obtained successively the dips and stresses due to 40, 58, and 76deg. F., as per table and diagrams. And working near the ground, with all the apparatus close to the eye, we were able to make the most minute observations without difficulty.

The moral of these experiments clearly is, that *the saving virtue of the line-wire is its elasticity*, and that a considerable increase of virtual elasticity, by means of spring shackles, or some such device, would be equivalent to a correspondingly considerable increase in the life of the line.

Mr. Preece has ignored Elasticity in his published table of dips and stresses; and has, in his speeches and correspondence, treated it as of no practical consequence. Yet Elasticity is the best friend Mr. Preece possesses in this connection. The wires which are erected in the summer at 43lb. tension, thanks to the kind offices of Elasticity, reach a winter stress of only 59lb., instead of the 80lb. assigned by Mr. Preece's table. And so it comes about that snowstorms and other exceptional stresses do *not* invariably wreck the lines, as they surely *would* if Elasticity were not a much more powerful friend of Mr. Preece's than he deems it. The partial salvation of the lines is now undoubtedly due to the limited extent of elasticity possessed by the wires themselves. Let this extent be sufficiently enlarged by the spring shackles, or other equivalent means, and the salvation, which is now partial, will be complete.

That the trouble of overhead wires as at present hung is *real* (and not "imaginary," as it has been called) is demonstrated, practically, by the enormous and, I believe, quite unnecessary outlay incurred by our Government in changing town wires from overhead to underground; and is still further demonstrated by the Bill now coming before Parliament, by which the telephone companies seek increased power of obtaining wayleaves over housetops. And outside of towns the proof that a real trouble is experienced, from the inability of the wires to save themselves by their own unaided elasticity, is afforded by the increasing tendency of modern telegraph engineers to shorten their spans. I do not know what the Post Office engineers are doing just now in this respect; but I do know that the telephone companies' engineers are reducing their spans greatly wherever practicable, and that the American telegraph engineers are doing so to a still greater extent. The forces of Nature must prevail; and, since it is coming to be a battle between multiplying posts or applying springs, we have, in the immediate future, another illustration awaiting us of "the survival of the fittest."

It is to the interest of the public service that the invaluable character of Elasticity, as the saviour of the telegraph wires, should be fully realised; and that rational proposals (such as those made by Sir Frederick Bramwell at the Manchester meeting of the British Association) for incorporating an additional quantity of this saving element should be *rationally tested* by the authorities who are responsible to the public for good inventions rejected, no less than for bad ones accepted. The subject is one on which a jury of engineers rather than of electricians should decide; as electricians are no more renowned for their proficiency in mechanics than are engineers credited with a knowledge of electrical science.

Telephone Manufacture.—The ss. "Gothenburg City" arrived at Antwerp on the 8th inst. from Newport News, Virginia, with 1,270 tons of walnut logs, consigned to the Bell Telephone Manufacturing Company. This cargo of walnut, which is one of the largest ever brought to Europe, comprising no less than 1,828 logs, will be used entirely in the manufacture of telephonic apparatus.

FORMULÆ FOR CONVERTERS.*

BY PROFESSOR GEORGE FORBES, F.R.S. (L. AND E.)

The modern transformer for electric lighting is an induction apparatus in which the primary coil is of high, and the secondary of low, resistance, consisting of two ring coils of insulated copper wire enclosed in an iron sheathing, so subdivided as to prevent the formation of local currents in the iron when subjected to the influence of alternating electric currents in the coils. The terminals of the primary are kept at a constant mean difference of potential. The secondary circuit includes the lamp circuit, and is of varying resistance. The iron is so situated with respect to the coils that there is no free magnetism; this simplifies the mathematical treatment of the phenomena.

It is required to predict (1) the magnetic induction in the iron, (2) the work given off to the lamp circuit, (3) the whole work absorbed by the apparatus, (4) the waste of energy when no lamps are in circuit, and (5) the effect which will ensue from varying the construction of the apparatus. The first of these has been approximately solved on the assumption that the permeability of the iron is constant.†

It is generally assumed that in such a system of electrical distribution the electromotive forces, the electric currents, and the magnetic induction are simple harmonic functions of the time. This would not be the case if the phenomenon called by Ewing "magnetic hysteresis" is taken into account, and in a preliminary investigation this must be omitted. Its effect in practice is insignificant so long as the magnetic induction in the iron is not high.

The notation now adopted is as follows :—

p_1 = number of turns in the primary coil.
p_2 = " " " secondary coil.
r_1 = resistance of the primary coil.
r_2 = " " secondary circuit, including lamps.
c_1 = current in the primary circuit.
c_2 = " " secondary circuit.
m = integral of the induction over the cross-sectional area of the iron.
$\rho = \dfrac{\text{mean length of lines of induction in the iron}}{\text{cross-sectional area of iron} \times \text{permeability}}$.
n = π × number of alternations of E.M.F. per second;
= 2π × " " complete periods of E.M.F. per second.
w_1 = work done in unit time by the primary current.
w_2 = " " " in the secondary circuit.
e = difference of potential of primary terminals.

C.G.S. units are adopted throughout.

Assume
$$m = \mathrm{M} \sin n t \quad . \; . \; . \; . \; . \; . \quad (1)$$
then
$$c_2 = -\frac{p_2}{r_2}\frac{dm}{dt} = -\mathrm{M}\, n \frac{p_2}{r_2} \cos n t \quad . \; . \; . \; . \quad (2)$$
and
$$w_2 = \int_0^1 c_2^2 r_2\, dt = \frac{\mathrm{M}^2 n^2 p_2^2}{r_2}\int_0^1 \cos^2 n t = \frac{\mathrm{M}^2 n^2 p_2^2}{2 r_2}\int_0^1 (1 - \cos 2 n t)\, dt.$$
The mean value of the periodical part is zero. Hence
$$w_2 = \frac{\mathrm{M}^2 n^2 p_2^2}{2 r_2} \quad . \; . \; . \; . \; . \; . \; . \quad (3)$$

Again,
$$\mathrm{M} \sin n t = \frac{4\pi}{\rho}(p_1 c_1 + p_2 c_2);$$
whence
$$c_1 = \frac{\mathrm{M}\rho}{4\pi p_1}\sin n t + \frac{p_2^2 n \mathrm{M}}{p_1 r_2}\cos n t \quad . \; . \; . \quad (4)$$
$$= \mathrm{C}_1 \sin (n t + a),$$
if
$$\mathrm{C}_1 \cos a = \frac{\mathrm{M}\rho}{4\pi p_1} \text{ and } \mathrm{C}_1 \sin a = \frac{\mathrm{M} p_2^2 n}{p_1 r_2}.$$
Again,
$$c_1 = \frac{\mathrm{E}}{r_1}\sin (n t + \beta) - \frac{p_1}{r_1}\frac{dm}{dt}; \text{ if } e = \mathrm{E} \sin (n t + \beta),$$
$$= \frac{\mathrm{E}}{r_1}\cos\beta \sin n t + \left(\frac{\mathrm{E}}{r_1}\sin\beta - \frac{p_1 \mathrm{M} n}{r_1}\right)\cos n t. \quad (5)$$

Equating coefficients in (4) and (5), we have
$$\mathrm{E}\cos\beta = \frac{\mathrm{M}\rho r_1}{4\pi p_1}; \quad \mathrm{E}\sin\beta = \mathrm{M}\, n\left(p_1 + \frac{p_2^2 r_1}{p_1 r_2}\right)$$
$$= \mathrm{M}\, n\, p_1\left(1 + \frac{p_2^2 r_1}{p_1^2 r_2}\right);$$
whence
$$\frac{\mathrm{E}^2}{\mathrm{M}^2} = \left(\frac{\rho r_1}{4\pi p_1}\right)^2 + n^2 p_1^2\left(1 + \frac{p_2^2 r_1}{p_1^2 r_2}\right)^2 \quad . \; . \quad (6)$$
also,
$$w_1 = \int_0^1 c_1 e\, dt = \mathrm{C}_1 \mathrm{E}\int_0^1 \sin (n t + a) . \sin (n t + \beta) . dt$$
$$= \frac{\mathrm{C}_1 \mathrm{E}}{2}\int_0^1 \{\cos (a - \beta) - \cos (2 n t + \beta + a)\}\, dt$$
$$= \frac{\mathrm{C}_1 \mathrm{E}}{2}\cos (a - \beta) = \frac{\mathrm{C}_1 \mathrm{E}}{2}(\cos a \cos\beta + \sin a \sin\beta)$$
$$= \frac{\mathrm{M}^2}{2}\left\{ r_1\left(\frac{\rho}{4\pi p_1}\right)^2 + \frac{n^2 p_2^2}{r_2}\left(1 + \frac{p_2^2 r_1}{p_1^2 r_2}\right)\right\} \quad . \; . \; . \quad (7)$$
$$= \frac{\mathrm{E}^2}{2} . \frac{r_1\left(\frac{\rho}{4\pi p_1}\right)^2 + \frac{n^2 p_2^2}{r_2}\left(1 + \frac{p_2^2 r_1}{p_1^2 r_2}\right)}{\left(\frac{\rho r_1}{4\pi p_1}\right)^2 + n^2 p_1^2\left(1 + \frac{p_2^2 r_1}{p_1^2 r_2}\right)} \quad . \; . \; . \quad (8)$$

When the actual figures pertaining to a modern transformer are inserted, it is found that the quantity $\frac{p_2^2 r_1}{p_1^2 r_2}$ is less than ·01; that the first term of the numerator in (8) is small compared with the second; and that the first term of the denominator is very small compared with the second.

The efficiency is found by dividing (3) by (7).

When no lamps are used on the secondary circuit, the rate of work done is, by (7) (r_2 being infinite),
$$\text{waste} = \frac{\mathrm{M}^2}{2} r_1 \left(\frac{\rho}{4\pi p_1}\right)^2.$$

It will be noticed that the efficiency of the apparatus depends on the first term in (7) being small compared with the second; hence n (or the number of alternations per second) may be diminished without loss of efficiency if ρ be diminished, or if the mass of iron be increased.

BY H. D. WILKINSON.

CHAPTER VIII.—*The Calibration of Current Indicators.*

(Continued from page 377.)

81. The relation between the angular deflections of a needle and the currents causing those deflections, in an indicator, is a most useful thing to be known about the instrument. The currents causing given deflections on any instrument may be directly proportional to those deflections, or they may vary as some known function of the angles of deflections, or there may be no settled relation between them at all. It is in the latter case that "calibration" is desirable, and the relation between the angular deflections and currents is generally shown by means of a curve, which can be referred to when it is required to know what is the strength of current corresponding to a given deflection. There are different methods of carrying out the calibration of an indicator, more or less suitable according to the resistance and sensibility of the instrument. We shall first take the simplest method, which can readily be applied to the calibration of high-resistance instruments when a few similar *low-resistance* cells are available. The internal resistance of a cell will be low when its plates are of large size and fixed near together. Almost any type of cell will do for this test, provided its plates are of large area, in addition to which the cells should not polarise; this latter difficulty, however, being very unlikely to occur, as the time of contact need only be very short to take a reading of the deflection, and the comparative high resistance of the instrument

Digitized by Google

would allow very little current to pass from the cells. The Thomson tray cells (Fig. 47) previously described in these papers are of very low internal resistance, varying from $\frac{1}{10}$th to $\frac{1}{2}$ an ohm per cell, and would be very suitable; or if some charged accumulators were available these would do better still, their resistance being only about $\frac{1}{50}$th of an ohm per cell.

Taking, in the first instance, a vertical detector of high resistance compared to the cells, it would be first connected to one cell in the manner shown in Fig. 47; the deflection might then be large or small according to the weight of the needle. If the deflection is only a few degrees we should proceed, after noting it down, to connect up two cells, then three, and so on till the needle was deflected to near the end of the scale, say to 85 degrees, noting down opposite each number of cells the corresponding number of degrees deflection. Now the currents are very easily calculated, each cell having a fixed E.M.F., and its internal resistance so low in comparison to that of the instrument that it may be neglected. An example of this kind actually taken of a vertical detector of 220 ohms resistance is here appended. The cells used were secondaries, or accumulators measuring 0·02 ohm and 2 volts per cell, and the readings taken were as follows:—

No. of Cells.	Deflection.	Volts at Terminals of Instrument.
1	10	2
2	42	4
3	64	6
4	75	8
5	81	10
6	85	12
7	87	14

Now, it is desirable to obtain some intermediate readings between 10 and 42 degrees and below 10 degrees, as a very wide difference in the deflections is noticed between one and three

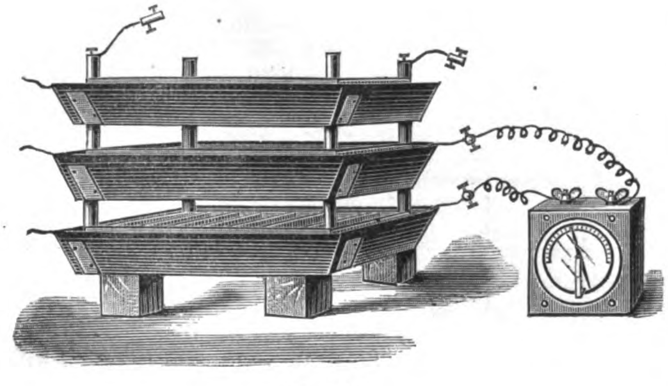

FIG. 47.

cells. We cannot get these intermediate readings by the cells alone, but must add a resistance to the detector to reduce the difference of potential at its terminals. First, it must be shown that the number of volts at the instrument terminals when connected direct to the cells is practically equal to the E.M.F. of the cells. By Ohm's law we have the current passing through the instrument is equal to the

$$\frac{\text{volts at instrument terminals}}{\text{resistance of instrument}}$$

and therefore the number of volts at the instrument terminals is always the product of the current and the instrument resistance. But the current is also, by Ohm's law, the

$$\frac{\text{total E.M.F. of battery}}{\text{total resistance in circuit}};$$

therefore, the number of volts at the instrument terminals is equal to the

$$\text{total E.M.F. of battery} \times \frac{\text{resistance of instrument}}{\text{total resistance in circuit}}$$

Now, if the instrument was connected directly to, say, 5 cells, the E.M.F. of battery would be $5 \times 2 = 10$ volts, and its resistance $0{\cdot}02 \times 5 = \frac{1}{10}$ ohm; and therefore the number of volts at the instrument terminals would be

$$10 \times \frac{220}{220\frac{1}{10}} = 10 \times \frac{2200}{2201},$$

where it is evident that the fraction by which the E.M.F. of 10 volts is multiplied is so nearly unity, that we practically have the same number of volts at the instrument terminals as we have E.M.F. in the battery. The reason is that the internal resistance of $\frac{1}{10}$th ohm is so small in comparison to 220 ohms, that it causes an inappreciably small loss of E.M.F. in the battery. This accounts for the third column given in volts. Now, to get the intermediate deflections in this case, extra resistances were added to the instrument, so as to produce respectively 1, $1\frac{1}{2}$, 3, and $4\frac{1}{2}$ volts at the instrument terminals. By taking one cell, and adding a resistance equal to the instrument, the potential difference at the terminals became

$$2 \times \frac{220}{220 + 220 + {\cdot}02} = 2 \times \frac{1}{2} = 1 \text{ volt};$$

and by making the extra resistance equal to one-third that of the instrument ($= 73{\cdot}3$ ohms) the volts at the terminals became

$$2 \times \frac{220}{73{\cdot}3 + 220 + {\cdot}02} = 2 \times \frac{3}{4} = 1\tfrac{1}{2} \text{ volt}.$$

Similarly to obtain 3 volts, two cells were connected, and the extra resistance made the same as in the previous case. This gave

$$4 \times \frac{3}{4} = 3 \text{ volts}.$$

For $4\frac{1}{2}$ volts at the terminals, 3 cells were joined up, the added resistance being the same as before, which gave

$$6 \times \frac{3}{4} = 4\tfrac{1}{2} \text{ volts}.$$

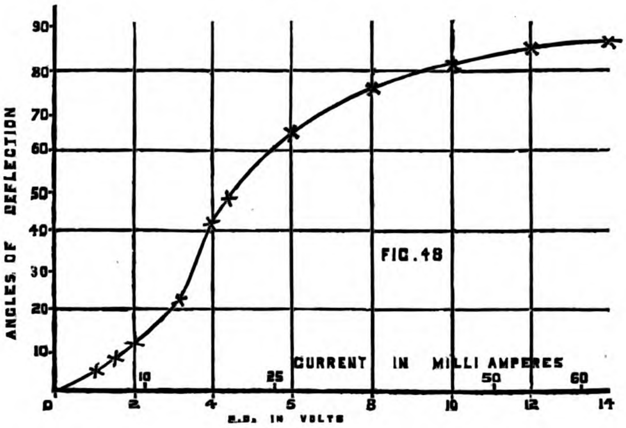

FIG. 48.

In any case it will be seen from the above that to obtain any given number of volts at the instrument terminals when low-resistance batteries are used as above, a resistance must be added equal to the resistance of the instrument multiplied by the following fraction—

$$\left(\frac{\text{E.M.F of battery}}{\text{number of volts required}} - 1\right)$$

The intermediate deflections observed with the above were then as follows:—

No. of cells.	Added resistance.	Deflection.	Volts at instrument terminals.
1	220	4	1
1	73	7	$1\frac{1}{2}$
2	73	22	3
3	73	48	$4\frac{1}{2}$

thus making eleven observations altogether, from which the curve in Fig. 48 is plotted. The angles of deflection are marked on the vertical ordinate, and the potential difference (P.D.) in volts at the terminals on the horizontal ordinate. The latter ordinate is also marked in units of current (milliamperes), the current in these units being simply the

$$\frac{\text{number of volts at terminals}}{\text{resistance of instrument}} \times 1000,$$

one milliampere being the $\frac{1}{1000}$th part of an ampere.

Now, since the denominator in the above is constant it is clear that the currents through the instrument are proportional to the volts at the terminals, and therefore the calibration curve connecting deflections with volts at the terminals is precisely the same as that connecting deflections and currents.

(To be continued.)

ELECTRIC TRACTION.

DIRECT CURRENT WORKING *versus* ACCUMULATORS.

BY MR. A. LINEFF.*

On the question of electrical transmission of power as applied to tramways, a rather vexatious problem presented itself. Should continuous conductors or accumulators be used? Electricians and non-professional people interested in tramways were divided into two distinct camps, theoretically hostile to each other. Unfortunately there were as yet no reliable data with reference to the life and cost of renewals of accumulators on tramways; but it was known that they were heavy. Yet sometimes even a rough estimation was of value for practical purposes, and he had recently prepared an estimate when giving his advice on a new tramway that was to be worked electrically.

He would compare the transmission of electrical energy:— A. By means of naked conductors suspended from telegraph-poles, which system would work well on tramways passing through open country. B. Underground conductors placed in a channel between the rails or on the side of the rails. C. Accumulators. As accumulators replaced only the conductor, he would leave out of the calculation all expenses relating to permanent way, generating plant, &c., and consider merely the cost of conductors as compared with the cost entailed by using accumulators. He would assume the line to be 1 mile long, with two cars for the accommodation of 46 passengers, running on it at an average speed of, say, 6 miles an hour. With the conductor system this could easily be accomplished with 30 amperes, at an actual pressure of 250 volts.

He took for conductor—

		£	£
A.	The cost per mile to be		200
B.	,, ,, ,, ... (which was a liberal allowance in each case; the figures had been taken from a *bonâ fide* tender.)		1,500
C.	When using accumulators 1½ ton of cells would be required per car; three sets, 4·5 tons, or two cars 9 tons, at £60	540	
	Increase in cost of cars, motors, &c., 50 per cent.	270	
	Total..................	—-	810

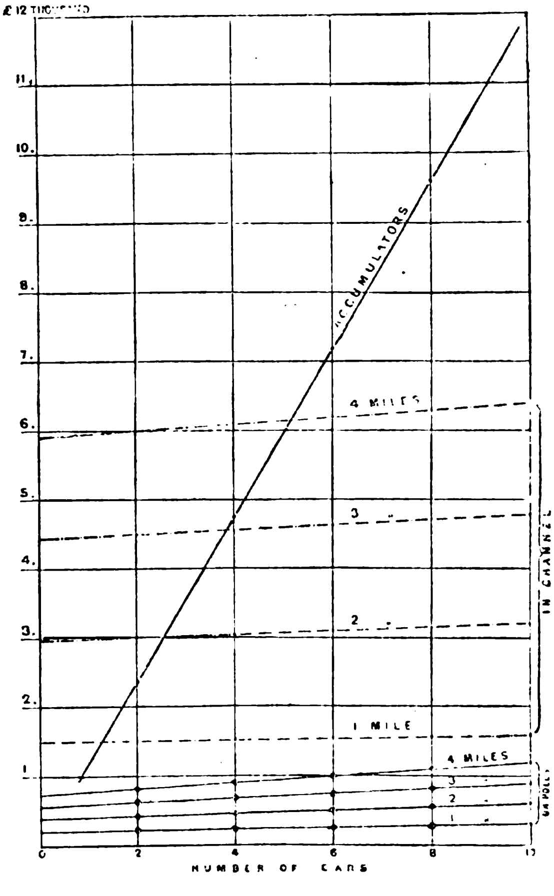
Say £800. Assuming interest and depreciation of conductors A and B at 10 per cent., and of accumulators at 30 per cent., which was rather in favour of the accumulators, the differences of depreciation in the two plants were 20 per cent. Now, in order to put both systems on the same footing as regarded depreciation, the actual cost of accumulators must be increased by the capitalised difference of depreciation of the two plants. Thus £1,000 invested in conductors would annually depreciate at the rate of £100; while, with accumulators, the loss would be £300, and would correspond to an outlay of £3,000 with a depreciation of 10 per cent. For this comparison, therefore, the actual cost of the accumulator plant must be trebled. It was clear that in case of an increased traffic, the capital outlay on the continuous conductor system would increase only nominally by the extra weight of copper to be added to the conductor. An allowance of £25 per mile for every two additional cars (30 amperes) would be ample. For accumulators the question was different; in this case, the cost of the accumulator plant must be multipled by the number of cars to be run. The following table was calculated for various lengths of line and various numbers of cars:—

COST OF CONDUCTOR AND ACCUMULATOR PLANT.

Length.	Two Cars.			Four Cars.			Six Cars.		
	A.	B.	C.	A.	B.	C.	A.	B.	C.
1 mile	200	1,500	2,400	225	1,525	4,800	250	1,550	7,200
2 miles..........	400	3,000	2,400	450	3,050	4,800	500	3,100	7,200
3 ,, ...	600	4,500	2,400	675	4,575	4,800	750	4,650	7,200
4 ,, ...	800	6,000	2,400	900	6,100	4,800	1,000	6,200	7,200

Length.	Eight Cars.			Ten Cars.		
	A.	B.	C.	A.	B.	C.
1 mile	275	1,575	9,600	300	1,600	12,000
2 miles	550	3,150	9,600	600	3,200	12,000
3 ,, ...	825	4,725	9,600	900	4,800	12,000
4 ,, ...	1,100	6,300	9,600	1,200	6,400	12,000

The values in this table had been used to prepare Fig. 9. The ordinates represented the cost, and the abscissæ the number of cars.



COMPARATIVE COST OF CONTINUOUS CONDUCTORS AND ACCUMULATORS.

FIG. 9.

The four thinner lines at the bottom of the diagram represented the cost of conductor placed on poles for 1, 2, 3, and 4 miles. The four dot-and-dash lines abave represented the cost of conductor in a slotted underground channel. The diagonal line across the diagram represented the cost of accumulators, and was independent of the length of the line, but was very much dependent on the number of cars running. This diagram showed:—(*a*) That wherever an aerial conductor could be used, the accumulator system could not compete with it, however small the traffic, if the length of the line did not exceed, say, 10 miles. (*b*) That for heavy traffic the accu-

* From the *Proceedings* of the Institution of Civil Engineers, being a speech delivered during the discussion on Dr. E. Hopkinson's paper on the Bessbrook and Newry Tramway

Digitized by Google

mulator system could not compete even with the expensive underground continuous conductor. (*c*) That in each case, where an increase of traffic might be expected, the continuous conductor was preferable, as a trifling extra outlay in copper imparted great elasticity to the line with regard to the number of cars which could be worked on it. (*d*) That the accumulator system could be advantageously applied in towns on comparatively long lines with a small number of cars running, which was, of course, an exceptional case. Fig. 9 did not pretend to give with great accuracy the actual cost of individual systems; but it showed at a glance the characteristic features of each, and their relation to each other with regard to the capital outlay. The application of electric traction to railways was a question of great importance. It was an open secret that the Metropolitan underground lines were needing a radical change. Not only was the public choked with a vitiated air; but, what was more to the point, the shareholders began to suffer through the competition of the omnibus and tramway companies. The railway engineer might certainly point with pride to the fact that the consumption of fuel on those lines was under 30lb. per train-mile; but what was the amount of useful work done for it? Take as an instance the Metropolitan District Railway. The weight of the empty train was 92 tons; of the locomotive 47 tons; of a full load of passengers, 31 tons. The average number of passengers per train-mile was only twenty-seven, or about 1·5 ton; add 50 per cent. to arrive at the actual number, which would bring the useful load to 2·25 tons, and the ratio of $\frac{\text{paying load}}{\text{dead load}} = \frac{2 \cdot 25}{139}$, or only 1·6 per cent. Railway engineers could not be blamed; they did everything to make their power-producing machine as economical as thought, care, and great experience could make it. But the power was not suitable for the purpose. In order to reduce the cost of fuel and wages,* the railway engineer had only one way open to him: to increase the size of the locomotive, and therefore to run heavier trains. The consequences were:—Crammed trains for a few hours in the day, and almost empty ones during the remaining hours; slow service, immense waste of power, enormous wear and tear of the permanent way by locomotive wheels, with a weight of about 15 tons on each axle, and so on. The whole system seemed to be an illustration of what the French termed in logic *cercle vicieux*. With an electric plant, the aspect of working a railway would be entirely changed. The power would be generated at a central station or stations, and therefore under most economical conditions, with the least expenditure of fuel, attendance, and stores. The trains could be reduced to one or two carriages, starting in the busy hours of the day at intervals of one minute, or even less, and of four to five minutes during the remaining hours. In fact, the whole train service could be arranged to a nicety in accordance with the average requirements of the traffic. A separate heavy locomotive would be useless, as the motor could be fixed under the car or on the bogie; this alone would increase the efficiency, or the ratio of useful weight to dead weight, to at least five times its former value.† The work of driving and firing would be simply reduced to the turning of the switch in the guard's compartment, and therefore a great saving of wages would be at once effected. Moreover, it must be remembered that a dynamo or motor was kinemetrically one of the simplest mechanisms, having merely two journals with a rotating shaft and no reciprocating parts or motion of any sort. As a consequence, the cost of repairs of an electrical plant must be much less than with locomotive power. He thought it was quite time for the two great metropolitan railway companies to look into the matter more closely, and to give means to the electrical engineer to work out the problem. An investment like this would be of much greater benefit than the extension of existing lines on the old plan.

* Mr. J. S. Jeans has given in "Railway Problems," p. 146, the following table of expenditure incurred for locomotive power in 1885:—

	London and North-Western.	Great Western.
Wages	57·0	56·7
Fuel	35·2	34·2
Water	1·0	4·6
Oil, Stores	6·7	4·4
	99·9	99·9

† To refer to the above example for the Metropolitan District Railway, the introduction of electricity as motive power would alter the useful work thus:—A train of two empty carriages, 20 tons; motors, &c., gear, 2 tons; full paying load, ninety passengers, or 6·6 tons. The efficiency with full load would be $\frac{6 \cdot 5}{22} = 30$ per cent., half load $\frac{3 \cdot 3}{22} = 15$ per cent., quarter load $\frac{1 \cdot 65}{22} = 7 \cdot 5$ per cent., as compared with 1·6 per cent., the present ratio.

ON THE HEATING EFFECTS OF ELECTRIC CURRENTS.*

BY WILLIAM HENRY PREECE, F.R.S.

(Concluded from page 387.)

SERIES II.

The second series of experiments was made to determine the relative effect of the sudden application of powerful currents on wires of different materials such as would occur if in practice a short circuit suddenly took place. An electromotive force of 100 volts was used, and there being no appreciable resistance in the external circuit but the wire, the latter was subjected to the blow of a momentary current of immeasurable strength.

Metal.	Gauge.	Remarks.
	inches.	
Tin	0·0185	Fused with a sharp report, and scattered molten particles quite 6 feet in all directions.
„	0·136	Fuse diffused little more than a large splay of metal.
„	0·136 (repeated)	This wire was enclosed in a porcelain box, covered by a glass plate. It fused with considerable flame. The glass was broken into fragments, and the porcelain box chipped. Some fiery particles were thrown about.
„	0·064	One inch of wire was put into an earthenware box. When fused, the particles of metal were securely imprisoned by the box to which they adhered. All the lead was resolved into globules.
Platinum-silveralloy	0·061	Molten particles were shot a distance of 9 feet.
Platinum foil	0·001 thick	Molten particles thrown about 4 feet.
„	0·001 thick, 0·512 wide	„ „ „
„	0·00025 thick, ½in. wide	This strip of foil was 1¼in. long. Sparks thrown a few inches only.
Aluminium foil	0·001 thick	Molten particles scattered about 9 feet.
„	0·004 thick, ½in. wide	Incandescing particles thrown upwards and around, but not more than 3 feet distant.
„	0·001 thick ½in. wide	Profuse particles, and some thrown 6 feet distant in a white hot state.
Silver foil	0·001 thick, ¼in. wide.	Not so much splaying as in last experiment.
Pure silver wire	0·017	No incandescent particles reached the ground. The wire was destroyed with a sharp report.
Zinc foil	0·003 thick, ½in. wide	Better than silver foil, no particles being scattered.
„	0·003 thick, ½in. wide 2 strips.	A few particles were shot about 4 feet; one was of considerable size.
Copper wire	No. 20 B.W.G.	Large incandescent globules scattered around for a distance of 4 or 5 feet.
Brass wire	No. 18 B.W.G.	This went off with a flash, and threw to a short distance a splay of metal which remained incandescent for some moments, and burnt a hole in the table.
Hard-drawn bright steel wire	No. 18 B.W.G.	Scintillating particles flew in all directions to a great distance. This was the most dangerous break of all the experiments.
Mercury	....	Considerable flame produced, and particles widely scattered.

The conclusions derived from these experiments were that the best metal to use for small diameters was platinum, and for large wires tin. Platinum fuses in a wax-like kind of way, without explosion or scattering of molten particles. Platinum has great advantages over other materials; it neither tarnishes nor deteriorates. It is easily soldered.

Tin behaves very much in the same way when its dimensions are large. But it is very questionable whether large wires should ever be used for fusible cut-outs. Owing to radiation the surface keeps cool and solid, while the centre is molten and liquid. It bursts with an explosion, and the incandescent particles are forced away radially in all directions with considerable energy.

Fusible cut-outs are effective but somewhat barbarous, and from the absence of any scientific inquiry into their character and judgment in their use, they have in the majority of instances become rather a source of danger than of safety.

* Paper read before the Royal Society, Dec. 22nd, 1887.

	10·74	12·10	1342·5
		Mean =	1512·27

The value of the constant "a" for the different metals is therefore:—

	Inches.		Centimetres.
Copper	11684 0	....	2886·0
Aluminium	7948·4	....	1964·0
Platinum	5258·0	....	1299·0
German silver	5203 7	....	1285·0
Platinoid	4860·7	....	1201·0
Iron	3190·9	....	788·0
Tin	1800 6	....	445·0
Alloys (lead and tin, 2 to 1)	1455·5	....	359·5
Lead	1512 27	....	373·5

The values in the second column are obtained from those in the first by multiplying the latter by $\frac{1}{(2{\cdot}54)^{3/2}} = 0{\cdot}247$.

Since $C = ad^{3/2}$ gives the fusing current of any wire of a given diameter d, inversely—

$$d = \left(\frac{C}{a}\right)^{2/3}$$

will give the diameter of the wire which will fuse with a given current, C. Very useful tables can thus be calculated which would be of service to the electric light engineer.

[Jan. 5, 1888.—In all these experiments the results obtained on wires finer than those recorded—viz., those below 10 mils—were excluded, because it was found that they did not follow the law of the 3/2 power. In the discussion which followed the reading of the paper Prof. Ayrton pointed out that this must be so, and that it followed from Mr. Box's researches of 1868* that the current required to maintain a fine wire of a given material at a given definite excess of temperature is approximately directly proportional simply to the thickness of the wire. This has been fully developed in a paper read before the Society of Telegraph-Engineers and Electricians, November 24, 1887 (*Journal*, Vol. XVI, p. 539).]

CORRESPONDENCE.

THE TERM "MAGNETIC RESISTANCE."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Though the notion of "magnetic resistance" may be in a way convenient in practical work, such as dynamo and transformer construction, I venture to differ with you with regard to the editorial note so far as to say that mathematical physicists will never adopt such a term.

The objection is that it is a false analogy. That Ohm's law does not hold in the case of iron is hardly the point. Ohm's law does not hold in the case of a conductor that heats; but that does not prevent our talking about the resistance of the conductor. People seem to have assumed that because there is a magnetising force and a resulting flux that the flux is a current. Electric potential produces a flux in an insulating medium, and this is called electro-static induction. Similarly, magnetic potential produces a flux, and this is called electro-magnetic induction. In the case of electric potential the induction depends on the inductive capacity of the medium. Similarly the magnetic induction depends on the magnetic inductive capacity or permeability. Iron is thus a magnetic insulator with an enormous coefficient of inductive capacity, and it is not analogous to a conductor.

Without being too critical I may call attention to the frequent improper use of German capitals. Maxwell used these to denote vectors, and they should not be used unless they are treated according to quaternion methods; or, at least, they should not be used indiscriminately for vector or scalar quantities. Thus M. Hospitalier's equation

$$\Phi = \frac{\mathfrak{F}}{\mathfrak{R}}$$

is from a strictly mathematical point of view nonsense. Of course this may be hypercritical; but M. Hospitalier lays himself open to criticism, to some extent, in adopting some of Maxwell's vector letters and misapplying others. Thus in the above equation Φ denotes the *flux de force*, or apparently the surface integral of the induction; $\mathfrak{F}$ denotes *la force magnétomotricé*, or the magnetic potential, Maxwell's Ω; and $\mathfrak{R}$ denotes *la résistance magnétique*, which appears to be μ multiplied by the area and divided by the length of the magnetic circuit.

Our grandfathers have told us that the Institute of Electrical

Engineers appointed a nomenclature committee; but the result has been little so far, and it is difficult to know who are on it.—Yours, &c., JAS. SWINBURNE.

THE CUTTRISS SIPHON RECORDER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In *The Electrician* of January 20th, 1888, you publish a letter from William Dickenson, of Heart's Content, in which he insinuates that I have no claim to the invention of the siphon recorder described in your issue of November 11th, 1887; also that I claim priority for the employment of permanent magnets and a siphon vibrator.

No such claims as the two latter ones can be found in the article mentioned, and I would certainly be the last person to make them, inasmuch as I worked on the construction of a recorder twenty years ago (in Sir W. Thomson's laboratory), in which permanent magnets were used to produce the magnetic-field. The first practical application of a siphon vibrator undoubtedly belongs to Mr. Pescod, of the Central and South American Cable Company. Now, what I do claim for my recorder is, that it is the most compact, the most readily adjusted, that the various parts can be removed and replaced as may become necessary more expeditiously and with less general disturbance than any other form of siphon recorder.

The signal coil is a new form requiring only one magnetic field, consequently the weight of the permanent magnet can be and is greatly reduced.

For the vibrator I claim that it is the only one constructed on correct scientific principles, that it works continuously and successfully on cables exceeding 2,500 knots in length, giving a line absolutely free from lateral vibrations, while at the same time the siphon is as free as though static electricity was employed as the motive power; with no other form of vibrator can this claim be made and sustained.

I therefore maintain that until the above remarks can be proven erroneous the right to claim the instrument under discussion as my invention is indisputable.—Yours, &c.,

CHAS. CUTTRISS.

Drexel Building, New York, February 7, 1888.

EXHIBITING INVENTIONS AT EXHIBITIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the notice in your issue of last Saturday respecting the Glasgow Exhibition, and in view of the several other exhibitions to be held this year in Brussels, Vienna, Munich, Melbourne, and elsewhere, will you kindly allow us through the medium of your space to caution inventors against the danger of exhibiting unpatented inventions under the 39th Section of the recent Patents Amendment Act.

This section is one of most misleading character, for while it purports to protect the invention during the exhibition, and to secure to the inventor unprejudiced rights against others, it now transpires, by recent decisions in the law courts, that the legal interpretation of the section is that it merely affords protection to the inventor as against *his own* acts, and that he is not protected against others copying, if they choose, his invention.

According to this interpretation, then, it is injudicious for any inventor to exhibit under the section in question, for while he, no doubt, acquires protection against the consequences of *his own* acts, he is simply exposing his invention for unscrupulous speculators to pirate, and probably deprive him of any benefits he may be entitled to in connection therewith.

The remedy is not to exhibit without first taking out provisional protection, a step which affords all the security desirable under the Patent Law.—Yours, &c,

J. K. FAHIE AND SON.

Patent Office, 10, Leinster-street, Dublin,
and 323, High Holborn, London, Feb. 20, 1888.

LIGHTNING DISCHARGE AT A CABLE STATION.—EFFICIENCY OF THE "SAUNDERS LIGHTNING GUARD."

The Eastern Telegraph Company's station at Porthcurno, near the Land's End, was visited on the night of the 14th inst. by a thunderstorm, which, although it only lasted about five minutes, was very severe.

The storm burst so suddenly that there was no time to put the cables to earth. In an instant the office seemed to be brilliantly illuminated, the sparks proceeding from the cable connections being so vivid as to dazzle the eyes, and in the test room the noise of the discharges was as loud as from a big electrical machine or the cracking of a whip.

The lightning appears to have struck near the front of the building without doing any damage to the structure, and passed through the test room. The land line connections are at the other side of the station, and nothing was noticed near their lightning protectors.

The recorder coils on the Vigo and Lisbon cables, which had Siemens lightning protectors only, were fused. It was at first thought that the coil of the Gibraltar instrument was fused also, but it is protected by a Saunders fine wire and tube protector, and to this fact its safety is attributed. The platinum wire was fused, and it did its work and saved the instrument, putting the cable to earth.

The Eastern Telegraph Company have often had reports of the efficiency of the Saunders lightning guard, which is in use at almost all their stations, but in this case the proof is so clear that in future it will in every case be used in addition to a Siemens plate guard.

MEETINGS OF SCIENTIFIC SOCIETIES.

TO-NIGHT (FRIDAY), February 24th.

SOCIETY OF ARTS.

8 p.m. Indian Section. "Facts Regarding the Religions of India, and their Influences on the Social Progress of the People." By Sir WILLIAM W. HUNTER, K.C.S.I., C.I.E., LL.D. The Earl of NORTHBROOK, G.C.S.I., will preside.

ANSWERS TO CORRESPONDENTS.

In reply to a correspondent, dating from "University College, Notts" (who omits to give his name), he should obtain Ayrton's "Practical Electricity," and Stewart and Gee's "Practical Physics;" Vol. I. "Electricity and Magnetism." For the more purely theoretical side he might consult Larden's "Electricity."

E.M.F.—*A letter awaits you.*

THE ELECTRIC LIGHT AND THE CITY.

In his speech at the Gas Light and Coke Company's half-yearly meeting reported in our last week's issue, Colonel MAKINS, the Governor of the Company, summed up the position of the rival illuminants by saying that "The electric light people have their sphere, and we have ours; and I do not think we need be afraid of anything they do or say." Nothing could be fairer or more sensible than these words; but, unfortunately, their natural interpretation has been falsified on the very first public occasion when their meaning was put to the test. At the meeting of the City Commissioners of Sewers on Tuesday last, the report of the Streets Committee recommending the adoption of the Electric Light for a certain area of the City was rejected—or, at least, referred back to the committee once again—by a majority of 36 to 17; and it seems to be generally admitted that the opposition was prompted and encouraged mainly by the Gas Lighting interests. For reasons which we will endeavour to make plain, the scheme submitted by the Anglo-American Brush Company, and approved by the Streets Committee (who have had it carefully under examination), cannot have been rejected on its merits; and the ostensible reason assigned for referring it back for reconsideration may be dismissed as unworthy of serious notice. An alternative proposal from the Maxim-Weston Company, or any other *bona fide* undertakers, might, indeed, be worth considering; but to drag in a competitor at the last moment, supported by arguments which tell against that or any other Electric Light company doing the work, shows pretty conclusively that the real opposition is directed not against the Brush Company's offer, but against invading the ground occupied by the gas company. Mr. SLY, who led the majority, strongly objected to granting a seven years' monopoly. As nobody could possibly undertake the job without having some sort of monopoly the objection tells equally against the Maxim-Weston Company, whose offer he professed to favour. We may take it, therefore, that, Colonel MAKINS notwithstanding, the gas interests are afraid of the Electric Light, and are doing

Digitized by Google

their utmost to keep the "sphere" of the City all to themselves.

We are not without hope that the decision arrived at on Tuesday will be reversed. For one thing, the alternative scheme said to be submitted by the Maxim-Weston Company will not bear a careful examination. We have not the slightest desire to back up one scheme more than another; and we are absolutely indifferent as to what company gets the contract provided it falls into competent hands. This view we believe will be shared by every one of our clients, many of whom would be quite able to light the City as proposed, but who would, nevertheless, be sorry to see the Brush Company deprived of this undertaking, which they are well fitted to carry out, and for which they have some prior claims over any competitors. The Brush Company have had these negotiations on foot for several years past, have spent a considerable sum in promoting them, and are entitled to special consideration from the City authorities. The company are favourably situated for performing what they promise, they have suitable premises in more than one locality in the immediate neighbourhood, and nobody doubts their competency to do the work satisfactorily. They have had as large, if not larger, experience of this class of lighting than any other electric lighting company in this country, and quite recently they installed at the Manchester Exhibition nearly three times the number of arc lamps now proposed for the City of London. Now it must be confessed that nothing of this kind can be urged in favour of the only other competitor in the field. The Maxim-Weston Company are proposing to employ lamps, and, we presume, machines also, about which very little is known at present, and their competency to carry out such a work as is contemplated in the City—public arc lighting for the streets, and incandescent lighting by private contract for indoors—has yet to be proved. Moreover, the Maxim Company's proposal, if Mr. Sly's account of it is correct, embraces the whole of the City, and involves a payment down of £15,000 for first cost, a condition which, coupled with the magnitude of the undertaking—800 lamps of 450 candle-power against 169 of the Brush arcs of 2,000 candle-power—seems to us to stamp the proposal as utterly unacceptable, and only calculated to serve the purposes of obstruction.

Were the case one of genuine competition between several schemes of equal merit, no one would have a word to say against the City authorities giving to them the utmost possible attention. But in the actual circumstances we feel bound to say the Brush people have some ground for complaint against the Commissioners on account of their dilatory and indecisive attitude towards this question. It has long been admitted that the City is very badly lighted, that it ought to be lighted much better, that the electric light is a desirable substitute for the present system, and that a great number of citizens would be glad to use the new illuminant if it were placed within their reach. Notwithstanding these undeniable facts, the one and only substantial argument which has prevailed so far to delay the introduction of the electric light on a permanent footing is that it will cost so much more. No doubt it will; but so would an increased supply of gas to light the City adequately—an increase which the public rather deprecate than desire. Without a considerable additional charge the City cannot be lighted properly; and the chief question remaining, after admitting the superiority of the electric light, is whether the terms offered by the Brush Company are fair and just? This, too, is not disputed—unless Mr. Sly's very questionable alternative can be said to dispute it—the general opinion of the Streets Committee, who have gone carefully into the figures, being that £26 per lamp per annum for 169 lamps giving 30 times more light than the present gas lamps, which cost quite half as much, is a price which by itself will not pay the Company for their outlay, their chance of a profitable return being in the private custom they expect to secure from shopkeepers, printing offices, warehouses, and the like. And this view of the figures is probably correct, judging by what is being charged elsewhere both in this country and in America. In some part of the States the tariff per arc lamp per annum is very much higher; in Philadelphia, for example, it is £40 and even in New York, where the area of operations is much larger and the ascendency over gas far more complete than is at all likely in this country, the charge averages nearly £20 and taking the States all round it ranges probably between these two extreme figures. One thing, therefore, is pretty certain—the City of London cannot have the Electric Light for less than what the Brush Company, trusting to private patronage, consent to charge.

We have just remarked that the competition of the Electric Light as an illuminant is far more serious in America than it is in England, where gas is much cheaper; and we could have wished that Mr. J. C. Bell, who moved the adoption of the Committee's Report, had appreciated this fact, and held his tongue about "the gigantic gas monopoly." The gas companies can no more be reproached for being gigantic than for being monopolists. That they are gigantic may be a good reason for their giving fair play to a not dangerous and much needed rival; but that they are monopolists in this relation is contradicted by the very terms of Mr. Bell's motion. The gas manufacturers have a monopoly for the supply of gas, that is all. No one proposes to confer a like monopoly on the Brush Company, although Mr. Sly talked as if this were the case. There are, as we have already stated, a great many private installations in the City, and neither with these nor with their further increase, except by open competition, can the Brush Company interfere under the terms of its seven years' concession. All that is conceded is the exclusive right to open up the streets for the purpose of laying down mains, and certainly nothing less than this could be accepted by the undertakers whoever they might be. It is to be hoped that these considerations may induce the City Commissioners of Sewers to reconsider their vote when next the subject comes up for discussion.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

New York, *Feb.* 11*th*, 1888.

With the nearer approach of spring, electric railways are beginning to attract more and more attention, and there is promise of greater activity in this field during the present year than ever before. Extremely interesting reports come to hand from Richmond, Va., where for some months past an electric railway has been in course of construction by the Sprague Electric Motor and Railway Company. This electric road is at once the largest and the longest ever attempted. It includes nearly 13 miles of track, and the main portion is double-tracked for a distance of about two miles. The overhead system is used, with ground return. The grades run up in some cases as high as 10 per cent., and there are no fewer than 31 curves. The main conductor is a copper wire $\frac{3}{16}$in. diameter, which carries a current of 500 volts. In order to maintain the E.M.F. constant, four-feeder wires are employed, tapping into the main line wire at different points. This line wire is carried by 30ft. poles 125ft. apart, and connects with the working conductor, which is suspended across the track at a height of 13½ft. from the ground. The trolley contact is employed, but I understand that the final

Digitized by Google

form has not yet been arrived at; the idea is to make contact from the underside of the conductor. The full equipment of this road will comprise 40 cars with two motors each. The motors have a nominal capacity of 7½ horse-power each, and will develop up to fifteen, thus providing ample power for a car heavily laden on the steepest grades and sharpest curves. The current for the motors is generated at a very fine station, located midway in the line, and fitted up with three large cylindrical return tubular boilers, three 125 horse-power high-speed engines of Armington-Sims make, and six Edison dynamos of 40,000 watts each. It will be seen from these details that the undertaking is one of great magnitude; in fact, it was admitted that it was impossible to work the road with horses, and it will be seen that the much vaunted cable would have had very little opportunity of demonstrating its merits. To operate such a road by electricity is no small triumph for the art, and for Mr. Frank Sprague personally. That gentleman in developing his system of stationary motors brought on a very serious attack of illness, and his condition at one time was grave; but no sooner was he halfway toward recovery than he put himself to the task of equipping this road, which had up to that time been in the hands of his staff. It is largely due to Mr. Sprague's own genius and efforts that the road is in its present advanced and encouraging state. It is practically a success to-day, in spite of the initial mechanical and electrical difficulties that had to be overcome, and all the troubles incurred in running on a new track badly laid in a clay soil, submerged by winter flood. The road is in active service to-day, and I understand that Mr. Sprague expects to have it in just such shape as he would wish, by the end of March. This is the first piece of the kind that he has undertaken in person, and he has used the opportunity to carry out one or two experiments the results of which will be of use in other and further work. Meantime another Sprague road in the south, that at Wilmington, Del., has just gone into successful operation.

Turning from Richmond to Pittsburg, we find the Bentley-Knight Electric Railway Company operating its new road with success in Allegheny City, the suburb of the smoky manufacturing centre. The Bentley-Knight Company, as you are doubtless aware, has been engaged for some time in elaborating its system, and is understood to have done some very thorough work, both in its experiments and in securing its comprehensive patents. Its strength may be inferred from the fact that the powerful Thomson-Houston Electric Company has entered into an arrangement with it, by which the said company is to furnish motors for the Bentley-Knight system, and to push the business through its 300 sub-companies. To return to Allegheny City. The road there, as in Richmond, presented some enormous grades to be worked, reaching in one part no less than nearly 10 per cent. The road also presents the interesting feature of being one in which both the overhead conductor and the conduit are used. The present equipment consists of four cars, each of which carries two 15 horse-power Thomson-Houston motors, and the trolley and the plough for overhead and subway contact. There are eight miles of conductors. The station is equipped with a 200 horse-power Buckeye engine and four Thomson-Houston generators, and natural gas is used under the boilers. The cars have made on the road a speed of from 15 to 18 miles an hour through snow and mud. The plough is said to work very well in the conduit, and is so constructed that it can be jerked out of the slot immediately. The success of the section of conduit in use at Allegheny City would augur well for the success of the system here, in New York City, whenever the company is able to overcome the legal difficulties which prevent it from operating its Fulton-street line. Fulton-street is one of the busiest thoroughfares in New York, and is greatly in need of a street car line. The company which is to use the Bentley-Knight system has a franchise for the road, has already laid its rails, and would like very much to put in its conduit and its steam plant; but other street railway companies, whose tracks it would cross, are displaying a dog-in-the-manger spirit, and will not give it right of way. In this emergency an appeal has been made to the Legislature, which will, it is to be hoped, break the deadlock. We have less engine storage cars running in New York City, but what is wanted to thoroughly advertise business is just such a road as this on Fulton-street. Of course when the electric light convention meets at Pittsburgh a week or two hence, the Bentley-Knight road there will be one of the centres of attraction; but not everybody interested can go to Pittsburgh.

I saw the other day a communication in one of the Boston papers, from its City of Mexico correspondent, with regard to the use of the electric light in the land of the Montezumas. He notes the use of two English systems at the capital, the Swan and the Crompton, and of three American, the Edison, Thomson-Houston, and Fort Wayne-Jenney. He says that of late there has been great competition among the shopkeepers in securing the incandescent light for their show-windows, and that the taste for the electric light is spreading to other cities in the Republic. The Edison light is in use in the offices and other public places. The Gas and Electric Light Company is putting in a Swan system with the pledge that the monthly bills of its customers shall not exceed their gas bills. Gas is sold at the rate of 21s. 8d. sterling per thousand. Some idea of the cost involved in the manufacture may be arrived at from the statement that coal costs £3 per ton sterling, and wood £1. 17s. 6d. per cord. It is extremely fortunate for the company that the climate of Mexico is not cold.

I made in my last letter some comment on the favourable attitude of the mayor of this city, Mr. Hewitt, with regard to storage batteries, electric light and electric motors, and I must speak well of him for the action which he has just taken with regard to telegraph schools. There are in this country a number of swindlers who impose on ambitious young people, advertising to teach them telegraphy in a few weeks, when they can take positions guaranteed at from £150 to £300 a year. These schools, I am sorry to say, flourish in all parts of the country, and as they do actually, in some sense, give instruction, and as their guarantees are purposely vague and indefinite, it is very hard to bring them within reach of the law. All those who are familiar with telegraphic work know that the lower ranks of the profession are very crowded, and that so far as any demand exists for new material it is best satisfied by that which is furnished in the telegraph offices themselves, in the messenger boys and others who grow up in the business from its very foundation, and, as they display aptitude, get their chances of promotion. But these facts are not known to the guileless youths who flock to the telegraph schools, and the consequence often is that, after spending money which they have pinched themselves and their friends to obtain, they find themselves without a position and in absolute want. Mayor Hewitt has, as I have said, tried to put down this swindle, and as the law could not help him, has resorted to the novel method of placing a policeman in front of the school, the duty of the officer of the law being to warn away all would-be pupils. A better method of shutting up such places could hardly be hit on, and it is successful. As the schools have to advertise themselves in the daily papers in order to attract victims, it is hard for them to conceal their whereabouts, and hence the proprietors are feeling intensely disgusted. They will not vote for Mayor Hewitt's re-election. It is to be understood that no objection is taken to what one may term legitimate instruction in telegraphy. Such, for instance, as that given at the Cooper Institute, the magnificent people's university, founded by Mr. Hewitt's own father-in-law, the philanthropist, Peter Cooper. But even such places, it is to be feared, turn out more graduates than telegraphy can find room for, and the consequence is that the salaries of the operators are kept down.

Associated Chambers of Commerce.—At the meeting of the Associated Chambers of Commerce this week resolutions were passed in favour of the control by Government of telephonic communication, and also the establishment of telegraphic money orders.

INCANDESCENT LAMP SWITCHES.

We herewith illustrate some new designs for incandescent lamp switches by Messrs. Fowler, Lancaster and Co., of Birmingham. Figs. 1 and 2 represent a pendant switch, which can be used with or without the lamp attached, the novel feature being that the lamp can be put on or off with the hand only. Fig. 2 represents the interior arrangement, from which it will be seen that a sliding bar of ebonite carries a cross-piece of metal, by which rubbing contact is made between two stiff springs connected with the terminals. In the second position, when the lamp is off, the two springs rest upon an ivory stud which passes through the sliding bar above the contact piece. In this position the springs are more widely separated. Taking the holder in one hand it is easy to slide the bar into either position with the pressure of the thumb. The outer case is made of white china. Messrs. Fowler, Lancaster and Co. also send for our inspection several other patterns of lamp switches and fuse blocks of good design and handsome appearance,

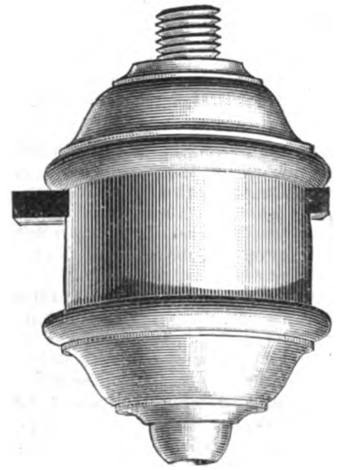

FIG 1.

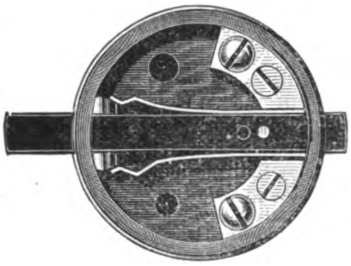

FIG. 2.

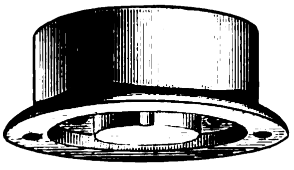

FIG. 3.

white china being used throughout. The backs of these switch-blocks are made with a deep groove to receive the bend of the wire as seen in Fig. 3. The fuse blocks are well adapted to receive the Cockburn fuse, with which some of them have been fitted.

ELECTRIC LIGHTING IN GERMANY.

At a recent meeting of the German Association of Gas and Water Engineers, Dr. Schilling read a long report on the position of electric lighting in Germany. Dr. Schilling commenced by remarking that, in dealing with the subject of the commercial development of electric lighting and its bearing upon the question of gas supply, attention should be called to the fact that the notable progress which the former system of illumination has made of late years, has been in great part due to establishments situated in districts outside the area served by gas works; although, at the same time, considerable advance has been witnessed in several German towns lighted by gas. He then proceeded to give statistics in support of these statements. It appears therefrom that in thirteen German towns the number of electric lighting establishments has risen, during the past two years, from 138 to 604; the number of arc lamps in use, from 591 to 3,280; and of incandescent lamps, from 10,403 to 50,469. It is in these thirteen large towns that electric lighting has made the greatest progress since its adoption. But there are still many small towns entirely without this kind of illumination. The number of gas burners used in the above-mentioned towns is about 1,221,882. Electric lighting, therefore, is in the proportion of about 4 per cent. to the latter figure. Taking all the towns in Germany, the proportion of electric appliances to gas burners is nearly 2 per cent. Two years ago it had not reached 0·5 per cent.

Berlin has the largest number of electric lamps. Some are served from two central stations belonging to the "Society of Shareholders of the Electric Supply Works of Berlin;" others from establishments started for the supply of blocks or groups of houses; others, again, from private establishments producing electricity by means of steam or gas engines. According to reports made up to April last, there were then altogether about 333 establishments, supplying 1,554 arc lamps of various types, and 22,363 incandescent lamps. Of these 333 establishments, 163 are carried on by the above-named society, and supply 116 arc and 9,306 incandescent lamps. At the time of writing Dr. Schilling's report, there were four large establishments for the supply of blocks of houses, viz.:—(1) The Shadowstrasse station, consisting of a steam engine of about 75 horse-power, supplying 4 arc and 612 incandescent lamps; (2) the Friedrichstrasse station, consisting of a steam engine of 200 horse-power, supplying about 5 arc and from 750 to 800 incandescent lamps; (3) the Passage station, consisting of three steam engines of 60 horse-power, supplying 52 arc and about 1,500 incandescent lamps—all set up by Messrs. Siemens and Halske. There is to be a fourth station—the Beuthstrasse—to consist of two engines of 80, two of 28, and one of 48 horse-power. This establishment is not yet in full working order; only 36 arc lamps, of 11 amperes intensity, set up in the Leipsigerstrasse, being supplied with the electric current.

Next after Berlin, Munich has the largest number of electric lamps, and in proportion to its importance has made the greatest progress in electric lighting. According to the latest reports, this city possesses forty-three establishments, supplying 167 arc and 7,936 incandescent lamps. This represents a proportion of 8 per cent. to the number of gas burners employed in the public lighting. In Munich there are also important electric establishments at the Imperial Theatre, which is lighted by 2,300 incandescent lamps; the Imperial Ministry of War, lighted by 800 lamps; the States Chamber, which has almost as many; several large breweries, which utilise their surplus steam for electric lighting purposes; and the markets on the quays of the Imperial Central Station. Eighteen of the above-mentioned establishments employ gas engines; and it should be pointed out that there is no central electric lighting station in Munich.

Hamburg has at present 70 electric lighting establishments, supplying nearly 300 arc and 4,500 incandescent lamps, of which about one-fifth are operated by means of gas engines. The most important establishment is a central station started in 1885 by a limited liability company, and able to supply nominally about 1,000 lamps; but as yet it is only in partial working order. Another establishment of nearly equal importance, and intended almost entirely for the supply of electricity to be used on the spot, is in an immense café; and another station, capable of supplying about 500 incandescent lamps, is in course of construction near the Bourse. Since 1882, the Municipal Council have established a station for supplying the Senate Chamber and its annexes; also one for lighting the Place de l'Hotel de Ville, which supplies 16 arc lamps; and another for lighting three covered wharves by means of 9 arc lamps. Within the Free Port, the warehouses are lighted by an establishment supplying about 50 arc and 4,000 incandescent lamps. This establishment was founded by the Free Port Warehouse Company, with the financial help of the Caisse Publique of Hamburg. Other establishments for the supply of the Free Port are projected. The Municipal Authorities also propose to set up a central establishment to serve 10,000 incandescent lamps, but capable of supplying twice this number.

In Vienna the most important electric lighting establishment, when Dr. Schilling prepared his report, was at the new Hotel de Ville, supplying 577 incandescent lamps; but it was to be enlarged so as to be adequate to supply 947 lamps. The two Imperial theatres are, as our readers are aware, lighted by the establishment of the Imperial Continental Gas Association. The city has besides 59 private establishments, comprising 90 dynamo-electric machines, which supply 248 arc and 5,846 incandescent lamps. Of these establishments 24 employ gas engines.

Coming to places of less importance, we find that Leipzig possesses 23 establishments, of which 13 employ gas and 10 steam engines. Of the total number, there are 21 private and 2 central establishments, supplying 256 arc and 3,459 incandescent lamps. Of the entire number of lamps, 1,410 are served by gas engines and 2,395 by steam engines. Crefeld has 44 establishments in all, supplying 175 arc and 3,209 incandescent lamps, being in the proportion of 6½ per cent. to the number of gas burners used. These lamps are distributed among 18 silk and velvet, 6 glass painting, and 8 dying works, and 12 other factories of various kinds. One special station supplies an arc lamp and 445 incandescent lamps. Five establishments, supplying together 9 arc and 441 incandescent lamps, employ gas engines; the others use steam engines. The exceptional conditions under which business is carried on at Crefeld, and more particularly the supersession of handwork by mechanical labour, which has become preponderant during recent years, constantly affords manufacturers facilities for installing the electric light. Cologne has 33 establishments, which supply 101 arc and 2,727 incandescent lamps. Sixteen of these establishments employ gas engines, and the remainder steam engines. Some central stations are in contemplation. Dresden has 30 establishments in all. They supply 157 arc and 2,379 incandescent lamps. In 14 of these establishments, supplying together 78 arc and 470 incandescent lamps, gas engines are employed; but in the others existing steam engines are almost exclusively utilised. At Barmen, electric lighting is almost in the same condition as at Crefeld. There are 28 establishments, supplying 226 arc and 2,251 incandescent lamps, nearly all in manufactories, and all employing steam engines. Chemnitz has 39 establishments, fitted up for the

Digitized by Google

most part in manufactories, and supplying 503 arc and 1,646 incandescent lamps. The electric lamps are in the proportion of about 4½ per cent. to the number of gas burners. But it must be taken into account that, among these electric lamps, there are a large number of the arc type. Breslau contains 27 establishments, supplying 123 arc and 1,932 incandescent lamps. Eleven of these establishments employ gas engines. The Municipal Authorities are desirous of setting up a central station; but the matter is awaiting the decision of a commission.

An important example of the competition of electric lighting with gas in Germany is furnished by the statistics relating to the group of towns supplied by the German Continental Gas Company of Dessau, of which Herr Oechelhaeuser is chief engineer. In eleven of these towns there are altogether 230 arc and 3,540 incandescent lamps in use, of which 13 of the former and 1,297 of the latter are supplied by machines actuated by means of gas engines. But 51 arc and 596 incandescent lamps were fitted up by non-consumers of gas. At Dessau there is a central electric station. The towns of Mulheim-on-the-Ruhr, Krakau, Lemberg, Essen, and Herbesthal had not any electric light at the time Dr. Schilling's report was prepared.

In the next two towns dealt with—Halle and Stuttgart—the theatres stand out conspicuously as favouring electric lighting. In the case of the former town, it was at the theatre that the new system of illumination was first adopted; the installation comprising 16 arc and 1,402 incandescent lamps. But beyond this there are within the lighting area at present only three manufactories illuminated by electricity; and they employ altogether 17 arc and 109 incandescent lamps. Outside the town, a paper mill and a brewery are lighted by electricity—the former by 10, and the latter by 18 arc lamps. The Royal Theatre at Stuttgart has nearly 1,000 incandescent lamps employed in its illumination; but the railway waiting rooms and platforms are lighted by arc lamps. Besides these there are six establishments which serve together 37 arc and 220 incandescent lamps. Coming north again, we find that in Brunswick, out of 15 private electric lighting establishments, 12 supply (together) 109 arc and 1,014 incandescent lamps. Not long since a project was started to light by electricity a block of houses very favourably situated for the purpose. Going westward towards the Rhine, we learn that in Elberfeld there are ten private establishments in operation; and that in the course of the winter of 1886 a company was successful in obtaining permission to light a block of houses with about 250 lamps. An attempt to secure a second concession for another part of the town failed. At the time Dr. Schilling was preparing his report, the Municipal Authorities were taking steps to establish a central lighting station on their own account.

In a group of towns (thirteen in number) lighted by the General Gas Company of Magdeburgh, there are six which have not yet adopted the electric light. In the remaining seven there are 51 arc and 581 incandescent lamps in use. Of the 22 towns supplied by the Gas Company of Thuringa, five are as yet without the electric light; while in the rest, 359 arc and 5,762 incandescent lamps are employed. But the greater number of these installations are in connection with manufactories situated, for the most part, beyond the company's lighting area in the several towns.

The whole of the other towns included in Dr. Schilling's report may be dealt with in a single paragraph. Carlsruhe has eight establishments, supplying 134 arc and 321 incandescent lamps. Three of these establishments are outside the area lighted by gas; and in two others gas engines are employed. Szegedin has four establishments, supplying 2 arc and 378 incandescent lamps. Offenbach has five establishments, supplying 69 arc and 219 incandescent lamps. In Heidelberg there are four manufactories lighted by 13 arc and 255 incandescent lamps. In three cases the dynamos are driven by steam engines, and in the fourth case by turbines. In Ratibor the manufactories include five installations, supplying a total of 24 arc and 312 incandescent lamps. Dantzig has seven establishments, supplying 11 arc and 300 incandescent lamps. In two of these cases gas engines are employed; and three are beyond the gas supply radius. In Deutz and Kalk there are six large manufactories, some lighted by both gas and electricity, and others by electricity only. A proposal was submitted to the authorities by an electric lighting company to set up a central station, and supply the public lamps gratuitously, on condition that a 12 years' concession was granted to them; but the offer was declined. In Charlottenburg, the villa of Mr. Siemens is lighted by 2 arc and 320 incandescent lamps; and the works of Messrs. Siemens and Halske by 22 arc and 50 incandescent lamps. Three private houses and a timber yard are also electrically lighted. Two manufactories at Hof are lighted by 292 incandescent lamps. At Mayence the platforms and some other portions of the central station of the Louis of Hesse Railway are lighted by 24 arc lamps; and there are three other establishments, having together 10 arc and 199 incandescent lamps. Salzburg has four establishments, supplying a single arc and 80 incandescent lamps, all by means of hydraulic power. A central station is contemplated. Traunstein has two establishments, using 5 arc and 75 incandescent lamps. Pforzheim has only two establishments, having about 50 incandescent lamps in all. In an ironfoundry in this town the use of arc lamps has been given up, after two years' trial. Kiel, as far as the town itself is concerned, has only one house lighted by electricity; but a freighter in the port uses some arc lamps for loading and unloading. On the other side of the port (which is not a part of the town) the works and storehouses at the Imperial Dockyard are lighted by arc and incandescent lamps; but they are only used to expedite the building of war ships. The electric light is employed at a large flour mill at Neumühlen; also at a dockyard, a manufactory, and an ironfoundry at Diedrichsdorf. All the war ships are lighted by electricity. Altona has at present only two places—pleasure gardens—electrically lighted; and in these cases arc lamps are employed.

ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION (LIMITED.)

At the moment of going to press we have received the following report of the Directors to be presented at the seventh ordinary general meeting, to be held at the Cannon-street Hotel on Friday, March 2nd, at 12 o'clock noon:—

2. During the past year there has been renewed activity in the electrical industry both at home and abroad, and although in the present state of electric lighting the business still calls for sacrifices out of proportion to the rewards it offers, there are indications that it is entering upon a new phase, and the Directors have reason to hope that the time is now not distant when the work done by the Corporation will be of a sufficiently profitable character to admit of the regular payment of dividends. The electric light is becoming more and more to be regarded as the light of the near future. Clubs, hotels passenger steamers, and war ships are not considered complete unless provided with the electric light, and in the case of theatres lighting by electricity is now recognised as one of the necessary precautions against danger from fire. Municipalities also, whether they own gas works or not, are showing an increasing inclination to encourage the establishment of central stations for the supply of electricity.

3. The Board have therefore continued to pursue the policy fully explained in the last report of developing the business of the Corporation, and of anticipating as far as possible the demands which will arise in connection with the carrying out of both public and domestic lighting on a large and commercial scale. With this view patent rights have been secured in connection with the distribution of electric currents of a high electromotive force to be distributed over large areas, and transformed to a low tension for domestic purposes. Considerable progress has been made by the Corporation, in common with others, with this system of distribution, as well as with that by means of accumulators, and the Board are now negotiating in several directions for contracts for the establishment of Central Stations for the supply of electricity. In matters of detail the Corporation have made appreciable advance during the year—in the further improvement of their machines and other apparatus, to the better organisation of the business, and in increasing the aggregate amount of their transactions. It is to be regretted, however, that owing to competition and consequent reduction of prices, profits have not increased in anything like the same ratio as the volume of business.

4. Among the satisfactory features of the year's work may be mentioned the lighting of the Royal Jubilee Exhibition at Manchester, by means of nearly 600 arc lamps, to the entire satisfaction of the authorities, and the success which attended this work has materially contributed to the Corporation receiving the contract for lighting the largest part of the forthcoming exhibition at Glasgow by means of 500 arc lamps. The Corporation also took an important part in the lighting of the American Exhibition in London. They have also carried out a large number of installations in clubs, theatres, on board ship, &c., some of the more interesting being the Lyceum Theatre, Edinburgh, the installations on board the Peninsular and Oriental Company's steamships "Victoria," and "Britannia," the hall of the Worshipful Company of Drapers, and the Royal Albert Hall.

5. The long pending negotiations with the Commissioners of Sewers for the lighting of a part of the City of London have been pushed forward with energy, and although a definite decision has not yet been arrived at, the Board trust that the matter will speedily be brought to a satisfactory conclusion.

6. It was stated in the last report that the Corporation had acquired the business of the International Electric Company in Austria-Hungary. During the year this business has been energetically developed, and there are good indications that it will constitute an important source of revenue to the Corporation. The firm of Kremenezky, Mayer and Co., in Vienna (under which title the Corporation are there trading), have carried out a variety of satisfactory contracts during the year, whilst at Temesvar, in Hungary, where upwards of thirty miles of streets are lighted by electricity, the Corporation have, since taking over the installation, materially increased the efficiency of the plant, and reduced the expenses of working, so that the balance is now on the right side, and the Corporation, having undertaken to supply the light to private consumers, are taking steps to extend the capacity of the works.

7. In the previous report the Directors referred to the litigation which was then pending in regard to the infringement by a few manufacturing firms of the patent held by the Corporation for compound

Digitized by Google

winding of dynamos. The Directors are glad to be able to report that the suit has been amicably settled out of court, Messrs. Crompton and Co. and their colleagues having accepted licenses from the Corporation upon the usual terms, and paid a sum of money in satisfaction of past royalties and legal costs incurred. In connection with this case it became necessary to take the evidence of Mr. C. F. Brush, in America, by commission, and Mr. Percy Sellon, the Corporation's electrician, who was entrusted with the mission, obtained evidence which, as was anticipated, confirmed the position of the Corporation with regard to this matter. Licenses to manufacture compound wound machines, under the Corporation's patent, have now been accepted by all the leading dynamo manufacturers in this country, including Messrs. Siemens Bros., Messrs. Crompton and Co., the Edison-Swan Company, Messrs. Mather and Platt, Messrs. Ellwell-Parker, Messrs. Greenwood and Batley, the India Rubber and Gutta Percha Company, Messrs. Goolden and Co., Messrs. Paterson and Cooper, and many others. One firm of manufacturers in Scotland have as yet declined to accept the very moderate terms demanded by the Board, and for the protection of the licencees of the Corporation the Board have lately instituted proceedings with a view to prevent the infringement of their rights.

8. The cross actions with the Edison-Swan United Electric Company, in which the Corporation were involved at the time of the last report are still pending, but are expected to be heard shortly. This litigation, while exceedingly to be regretted from its serious character to your interests, is, however, of far graver importance to the Edison-Swan Company, involving as it does the validity of the most important of their incandescent lamp patents, which, as would appear from their balance-sheet, stand at about £300,000, and upon which they rest their claims for an absolute monopoly of lamp making. The Board take this opportunity of placing on record their regret that their efforts to bring about an amicable settlement, consistent with your interests, have failed, and that everything points at present to the necessity of the case being submitted to the final decisions of the Courts of Law. The Board have, however, given their careful consideration to the matter, and have spared no trouble or expense to ensure success in the Law Courts, and the great strength of the evidence they have been able to collect, combined with the high legal and scientific advice by which they are guided, enable them to state their full confidence in the result.

9. The Bill introduced last session by Lord Thurlow to amend the Electric Lighting Act of 1882, based as it was in a large measure upon the evidence taken by the Select Committee of the House of Lords in 1886, was very favourably received, and passed by that House, the Prime Minister expressing the opinion that the enterprise should be allowed full scope, that all obstacles which had hitherto impeded it should be removed, and that terms should be offered which experience had shown capitalists would accept. The prospects of carrying the Bill through Parliament were therefore very good, had it proved possible to proceed with it in the House of Commons last Session. The Bill has been, however, reintroduced by your chairman, and there appears a reasonable prospect that it will become law this Session.

10. The capital account shows an increase of £34,939. This is due to carrying into effect the agreement with the International Company, already referred to, which involved the issue of 1476 fully paid shares, and to the issue of 1,354 new shares, under the resolution passed at the last meeting, giving the Directors power to issue new capital for the purpose of developing the business. Owing, however, to the fact that this new issue was not largely responded to at the time, the Directors thought it expedient to make a call of £1 per share upon those shares upon which the sum of £3 only had been paid.

11. The increase in the patents, development, and goodwill account of £3,580, is due mainly to the re-acquisition from the Eastern Electric Light and Power Company, in liquidation, of the Brush and Lane-Fox patents for the whole of the Indian Empire, exclusive of those for the Presidency of Bombay and the Nizam's Dominions, which had already been disposed of by the liquidators. The increment includes also the unrealised balance of the assets realisation accounts, which appeared in previous balance-sheets in connection with the absorption of the Great Western and Brush Midland Electric Light Companies, and which has been so dealt with in accordance with the principle laid down at the time of taking over those Companies, and the payments during the year for up-keep of patents.

12. It will be seen from the balance-sheet that there is a marked increase in the amount owing to the Corporation, which evidences the larger volume of business.

13. It will be perceived that, despite the larger operations conducted during the year, the general charges show a reduction of about 5 per cent. Several of the economies effected by the Directors now appear in the accounts for the first time; amongst these may be mentioned a reduction in comparison with the previous year of nearly £500 in carriage and freight, owing to an alteration in the classification of electric apparatus, which was conceded by the railway companies in the early part of the year, as the result of representations made by the Corporation. The Directors have also been successful in effecting several other and larger economies, which however are not yet reflected in the accounts. Among these may be more particularly mentioned the surrender of the lease of the premises at Portpool-lane, and of the recent sub-letting the Borough-road works.

14. The item of gross profit, which shows a substantial increase upon last year's figure, includes the amount of £3,132, being the estimated value of the fully paid shares in the International Company held by the Corporation, and which were relinquished as part consideration for the Austro-Hungarian business. The gross profit strictly due to the current business shows an increase of about 12½ per cent. The Directors propose that of the balance of profit £2,500 be added to provision account, and that £2,562. 12s. 1d. be carried forward to next account.

15. The Directors, following the precedent of numerous other industrial undertakings, have, after mature consideration, decided to adopt the principle of remunerating the chief officers in proportion to the net profits distributed by the Corporation. The arrangement is that an amount equal to 10 per cent. of the dividend declared shall be set aside as a fund to be divided, in proportion to salary, amongst the officers from time to time nominated by the Board under specified conditions. The Board are satisfied that the adoption of this plan will, in view of the appreciation expressed by the staff, have results highly beneficial to the proprietary, and the Board therefore cordially recommend it for adoption by the shareholders.

16. Owing to pressure of other engagements, Lord Sudeley found it necessary last spring to vacate his seat at the Board, and in July last Major-General Webber exchanged the position of managing director for that of consulting technical adviser, an office which in view of the immediate prospect of street and private lighting contracts, is one of daily increasing importance to the Corporation.

17. The Directors who retire this year by rotation are Mr. J. S. Sellon and Mr. J. B. Braithwaite, jun., who, being eligible, offer themselves for re-election. Messrs. Cooper Brothers and Co., the auditors, also retire, and offer themselves for re-election.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

The discussion on Mr. Kapp's paper on Transformers, and that of Mr. Mackenzie on the same subject, was commenced on Thursday, the 16th inst., Mr. W. H. Preece, F.R.S., in the chair.

Prof. AYRTON congratulated the authors upon their most interesting communications on a subject which was all important at the present time. He agreed with Mr. Mackenzie that a good deal of credit was due to Messrs. Gaulard and Gibbs, not for having invented a new method of distributing electrical energy, but for having drawn attention in an experimental way to that method at the Exhibition in the Aquarium in 1882, and for having persistently worked at the system. Many of them who saw the secondary generator at the Aquarium had no idea that in a few years it would form the system employed on the largest distribution of electrical energy in this country. Perhaps one reason why some of them did not appreciate at once the full importance of the employment of transformers was because they felt that when the measurements shown them were made so extremely incorrectly, possibly the system might be as unsatisfactory as the methods employed to measure its efficiency. Of course, that in no way detracted from the advantages of transformers, and he merely put it forward as a reason why he and his colleague, at any rate, did not fully appreciate at once the importance of transformers when Messrs. Gaulard and Gibbs exhibited their transformer at work in 1882. For example, the potential difference at the terminals of the transformer was then measured by means simply of a high resistance dynamometer, and that was multiplied by the current as measured by a low-resistance dynamometer, and the conclusion was at once jumped to that the product measured the watts put in or the watts given out, as the case might be, and in this way an efficiency was arrived at which might or might not have some connection with the true efficiency of the transformer. *Two* errors were made in that sort of measurement—to measure alternating volts with a high-resistance dynamometer was wrong; and to multiply the volts, even if correctly measured, by the current did not give the watts if the circuit contained self or mutual induction any more than the mean pressure of the steam in the cylinder of an engine multiplied by the number of revolutions per minute gave an answer proportional to the horse-power developed by the engine independent of the time the steam was cut off at each stroke. Therefore one felt, in 1882, more inclined to be guided by the fact that the core of the transformers was extremely hot in concluding that the system, at any rate as it then stood, was not particularly good, rather than by the results of experiments which were obviously incorrect. Nevertheless it did seem, in spite of that, that the system, as now developed, was an extremely good one. That was shown by the fact that it was used very extensively, as described at the end of Mr. Mackenzie's paper, in the United States. The next point that perhaps would suggest itself in this discussion was the question of safety to life. Of course they were dealing, or might be dealing, with a very high potential difference in the primary. How could they take care in the easiest way to avoid danger when people touched the secondary? A very ingenious device, due to Mr. Kent, was described by Mr. Kapp, and he also showed an equally ingenious arrangement of Captain Cardew's. It appeared to the speaker and his colleague that there was a far simpler device—a device merely consisting, as indeed was suggested by his colleague and himself some years ago, of putting one wire of every secondary to earth. Proper insulation was established between the primary and secondaries, and it did not affect the insulation of the primary circuits in the least, whilst it ensured perfect safety in the secondary arrangement without the use of any particular fuses or automatic motive device. It also had this advantage, that it prevented their getting a shock from the electrostatic capacity of a transformer, which might be considerable. It had been rather held by the authors of the papers that it was impossible to use

Digitized by Google

transformers *in series* if they wished to maintain constant potential difference at the terminals of the secondary when the resistance of the secondary circuit was altered; that is to say, if the number of lamps in parallel in the secondary circuit was varied. There was, however, a method of producing constant potential difference in the secondary with constant (mean alternating) current in the primary, which it appeared to him would lead to good results. The method was analogous with the compound-wound dynamo. In a compound-wound dynamo they had a series coil, which increased the magnetisation of the field-magnet when the current of the outside circuit was increased. They could get exactly the same thing with transformers. Supposing the secondary coil S (Fig. 1) were joined in the ordinary way to the lamps L, let there be in addition a second induction coil, S′ T, the primary of which S′ was in series with S and the secondary T, so joined up that it added a potential difference to the secondary circuit and added the greater potential difference the greater the current passing through the secondary. That arrangement was exactly the arrangement of a compound-wound dynamo; the tertiary coil would correspond to the series coil of the compound-wound dynamo. That was to say, a constant current passing through the primary coil P, would produce a constant electromotive force in the secondary S, and a potential difference would be added to the secondary circuit, the added potential difference being the greater the greater the current in the secondary circuit S. At any rate, he believed it might be possible by such an arrangement to do this, and so obtain a transformer capable of working in series. That idea occurred to his colleague and himself some three or four years ago, but as they found great difficulty in working out the currents in the primary, secondary, and tertiary coils mathematically, they thought they should do better by resorting to experiments. An apparatus was made, and, indeed, it was for these experiments that the little voltmeter which they brought before the society at the end of last year was originally devised. Their transformers were little things, and so they found it was necessary to measure a few volts—alternate potential difference—accurately, and therefore they wanted a voltmeter to measure four or five alternate volts accurately. When their experiments were about to start he came across an account published, if he remembered rightly, by Messrs. Gaulard and Gibbs, putting forward exactly the same device which those gentlemen had then just covered by a patent. He would be very glad to hear from Mr. Mackenzie whether this system was seriously tried. Had he not come across this description of a precisely similar method of compounding transformers, he and his colleague would certainly have pursued the matter, but they left Messrs. Gaulard and Gibbs to do it, and, curiously enough, nothing more had been heard of it. He was very glad to see that the idea of magnetic lag, which means a retardation of iron to be magnetised, was gradually gaining acceptance, especially in consequence of the admirable work that had been done on this subject by Prof. Ewing. The idea of magnetic lag, quite apart from Foucault currents in the iron, was put forward some years ago in that room in the paper, prepared by himself and his colleague, on electro-motors and their government, and the conception was used in all the calculations they made. This conception was somewhat laughed at by writers in some standard books. Their names were held out to reproach as having brought forward an idea of a magnetic lag which was something different from a lag due to Foucault currents, and which could not be entirely removed by any amount of lamination. Now, however, that the Greek name *hysteresis* had been given to the lag, the classically-educated Englishman was willing to believe in it.

FIG. I

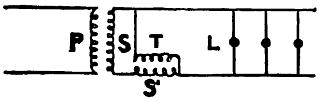

FIG. 1.—Ayrton and Perry's proposed self-regulating transformer for use with transformers in series on the main circuit. P. Primary coil, with constant (mean alternating) current. S. Secondary coil joined up to lamps L. S′T. Auxiliary regulating transformer, S′ the exciting coil in main secondary circuit, acting as primary to coil T. When the potential difference at the terminals of S falls off by reason of increase in the current through S, this increase of current passing through S′ excites a larger E.M.F. in T, which thus adds a potential difference to the lamp circuit, compensating for the falling off of the potential difference set up by the main secondary coil S alone.

He had spoken about wrong ways of making measurements of the efficiency and power given to transformers. Now he would say a word about the right ways of making such measurements. He was interested in doing this because, through the kindness of Mr. Kapp, who had lent him one of his transformers some time ago, a considerable number of experiments had been made by the third-year students at the Central Institution during the past few weeks. The students had worked at the subject with the most laudable perseverance, in spite of the very considerable number of difficulties which they had to overcome. There was only, as far as he knew, one electric method for measuring the power given to a circuit which contained self or mutual induction. The method was a method employing the quadrant electrometer. It was a method which Dr. Hopkinson employed in measuring the efficiency of Gaulard and Gibbs' transformers on the Underground Railway some few years ago. Let A B (Fig. 2) be the circuit possessing self or mutual induction, or both, the power given to which it is desired to measure. Place in series with this a *non inductive* resistance, B C, of known value r ohms, and send a current through the two by means of the dynamo A. Join the pairs of quadrants of an electrometer to the points A and B, and the needle to C; then if A, B, and C represent the potentials at any moment of the three points, and if D be the steady deflection of the electrometer

$$D=\frac{k}{2\tau}\int_0^{2\tau}(A-B)\left(C-\frac{A+B}{2}\right)dt,$$

where τ is the interval between two alternations. Next, join the needle to the point B, and let a steady deflection, d, of the electrometer be now obtained; then

$$d=\frac{k}{2\tau}\int_0^{2\tau}(A-B)\left(B-\frac{A+B}{2}\right)dt.$$

Consequently,

$$\frac{D-d}{rk}=\frac{1}{2\tau}\int_0^{2\tau}(A-B)\left(\frac{B-C}{r}\right)dt.$$

Now the expression on the right-hand side is the mean value of the true watts given to the circuit A B, therefore $\frac{D-d}{rk}$ measures this mean value of the true watts.

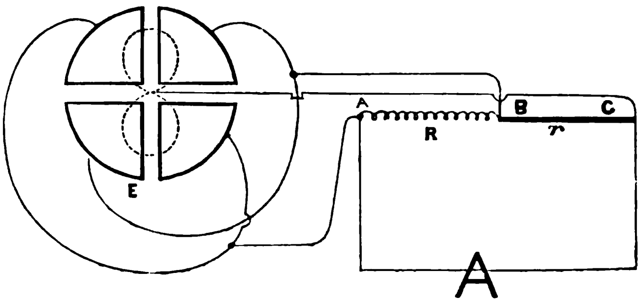

FIG. 2.—R. Inductive resistance to which power given by alternating current is to be measured. r. Inductive resistance. E. Electrometer. A. Alternating current dynamo.

It was rather interesting, because this method occurred simultaneously to Prof. Fitzgerald, of Dublin, and to the speaker during the Paris Electrical Congress of 1881, while listening to M. Joubert's paper on the measurement of alternating volts with an electrometer, which, of course, was a very much simpler thing. The use of the electrometer to measure volts only did what a Cardew voltmeter would do. The use of an electrometer to measure power, given by an alternating current to a circuit possessing self or mutual induction, did what no other instrument would do. But though the method was theoretically perfect, it had distinct practical objections. The first objection was that another resistance B C (Fig. 2) had to be put in series with the conductor A B, in which the power expended was to be measured, and, of course, a certain amount of power was wasted in this wire, B C. That did not interfere with the accuracy of the experiment in any way, but it might be inconvenient to have to waste any power in a circuit previously worked up to its limit. But there was another more serious objection which he was not aware of up to the last couple of years. Their formula was worked out on the assumption that the ordinary law of the electrometer, as given, for example, by Clerk Maxwell, was true. The law of the electrometer, as given by Clerk Maxwell, was that the deflection of the needle of an electrometer was proportional to the difference of potentials between the quadrants multiplied by a term containing the potential of the needle, minus half the sum of the potentials of the quadrants. Unfortunately, as experiments made at the Central Institution had shown, it was an exception for any given electrometer to satisfy this formula. He would not go more into that at the present time, because it would form the subject of a subsequent communication. He merely wished to warn any of them who were going to use the electrometer that, although this method was perfect on the assumption that the formula given in books was the formula for the electrometer, it naturally was not so perfect if the formula was wrong; so that even this method, pretty as it was, was at fault. Well, then, there was only one other method that he knew of by which they could measure the power and efficiency of a transformer, and that was the calorimetric method. They wanted to measure the power given to the transformer, and the power given out by the transformer. The power given out by the transformer could be easily measured. The secondary circuit would give current to, say, incandescent lamps, and as there was no lag in this part of the circuit the power could be measured merely with a voltmeter and dynamometer. But they could not employ that method to find the power given to the primary. They could, however, do it indirectly in this way:—Put the transformer in a calorimeter; first put it in a box, close it up water-tight, then put it in another box, which must be water-tight at the bottom, but need not be water-tight at the top; arrange a definite resistance in the secondary circuit, and send a definite current through the transformer for a certain time, and allow water to enter, say, at the bottom of the calorimeter and to flow out at the top, and measure the temperature of the entering water with a thermometer and the temperature of the water which leaves, and keep the current flowing until everything has become quite steady—until the temperature of the water as it flows out of the calorimeter ceases to rise, which in some case took as long as three and a half hours. Then, quite apart from the

Each test given in the above table is the mean of five or six consistent results.

Efficiency $\frac{100\,h}{\sqrt{a^2 \times b^2}}$ neglects the lag due to the self and mutual induction of the transformer.

Efficiency $\frac{100\,h}{j}$ neglects the lag due to the self and mutual induction of the transformer; also the lag in the fine wire coil of the watt meter due to its self induction.

Time of an alternation in all the experiments was about $\frac{1}{180}$th of a second.

specific heat of the transformer and the calorimeter, and so on, they had at once the power wasted in the transformer. Supposing W was the weight of water in grammes which flowed out of the calorimeter in a time of, say, *t* seconds, and suppose T was the difference of temperature between the entering water and the leaving water, which he had supposed to have become quite steady, then the power in watts wasted in the transformer and given out in the form of heat was equal to W, the number of grammes of water, multiplied by difference of temperature T divided by the time in seconds *t* into a constant ·239. That gave them the power in watts that was wasted in the transformer. That added, of course, to the power given out by the secondary, which was obtained by electrical measurement, gave them the power put into the primary, and they had then the whole measurement with a considerable amount of accuracy. Let him repeat, power given out by the secondary was accurately measured, provided that the secondary was attached to incandescent lamps or to something having no self-induction nor mutual induction, by the square root of the mean square of the volts multiplied by the square root of the mean square of the current; that was to say, measured by the reading of the Cardew voltmeter multiplied by the reading of the Siemens dynamometer. That was the power given out in watts. The power wasted was measured by the formula already given. The ratio of the watts obtained in secondary to the sum of the two is, of course, the efficiency. Well, that method had given them very fair results. He had compared these readings with those obtained by putting a dynamometer and a voltmeter on the primary circuit. For the interest of the thing, they had also an ordinary wattmeter in circuit, the thick coil in series with the primary and the fine coil a shunt to the mains. Now, it was interesting to see the sort of results that were obtained on the different systems of measurement, especially as they knew which results were true and which results were more or less correct. In the first case, the circuit outside was broken. That is, there was no current in the secondary circuit. This particular transformer was an exact *fac simile* of a small transformer which Mr. Kapp had on the table last time. He might mention that Mr. Kapp's mode of rating transformers was an extremely satisfactory one. Very often when a new apparatus was devised the nominal power was stated in excess of what the real power was. But transformers, at any rate Messrs. Kapp and Snell's transformers, were on a par with the steam engine, and that was that the real power developed was far greater than the nominal. He did not know whether his dynamos were equally good; but if so they must be extremely good. This was the two horse-power transformer nominal, which did not mean, he was happy to say, that it gave one horse-power. It meant that you could get three out of it, or even four without undue heating (applause). In the first case the volts at the primary circuit were 184·3, the volts at the secondary—the circuit being open—were 94·5. Now let them see the enormous differences of the power as measured in the different ways. The watts put in as measured by the voltmeter and dynamometer were 147. The watts put in measured by the wattmeter were 98·5. But the actual power put into the whole circuit was only 53 watts. Therefore the two first were enormously too large; and they could see why they were too large. They were too large because, when the secondary circuit was broken, the effective self-induction of the primary coil of the transformer was very much larger than when the secondary circuit was closed, and the errors of both methods became immensely magnified. Of course, in this case, since the secondary was open, all the power put in was wasted in the heat. But the real watts given to the primary, as determined by the calorimeter, was 53·2. The other methods indicated, then, about from two to three times too much. Of course, as the secondary circuit was closed and less and less resistance was put in, the readings given by the wattmeter as well as the product of indications of the voltmeter and dynamometer became nearly equal to the true watts, but they never, even for the maximum power, became equal. For example, when 2,963 watts were actually being given to the transformer, which was about 4 horse-power, the product of the square root of mean square of volts into square root of mean square of amperes gave 2,995 watts, while the wattmeter gave 3,277 watts as the power put into the transformer. The readings obtained from the voltmeter and the dynamometer were higher than the true watts put in, because lag, due to the self and mutual induction of the transformer, was ignored altogether. The wattmeter readings were higher than the true watts put in, because, not merely was the lag due to the self and mutual induction of the transformer neglected, but the lag in the fine wire coil of the wattmeter, due to its self-induction, was also ignored. That led him to investigate the question as to whether the wattmeter ought to give them an answer nearer the truth than the product of V squared into C squared; and the result that he had obtained, approximately at any rate, was this:—The wattmeter might or might not apparently give them an answer nearer or farther away from the truth than the reading from the dynamometer and the voltmeter. A rough calculation showed this was what was obtained with a wattmeter. Take a wattmeter like a Siemens wattmeter, which had practically no mutual induction, but had some self-induction; then if such a wattmeter were employed to measure power in a circuit having self-induction this seemed to him what would be obtained. If τ was the time of an alternation, r the resistance, and L the coefficient of self-induction of the fine wire circuit of the wattmeter, r' and L' the resistance and self-induction of the circuit the power given to which it was desired to measure, then the reading of the wattmeter, compared with the true power which they wanted to measure, had this value $\frac{r}{r'} \times \frac{\tau^2 r\, r' + \pi^2 L\, L'}{\tau^2 r'^2 + \pi^2 L^2}$. It was possible, by putting but a few convolutions on the suspended fine wire coil of the wattmeter, and using for the greater part of the resistance of the fine wire circuit a stationary non-inductive resistance, to make L the coefficient of self-induction of the fine wire circuit of the wattmeter very small, but unless it were made absolutely nought, the term $\pi^2 L\, L'$ might be large in consequence of the largeness of L, and the expression would be the greater the greater L' was. So that, in other words, they might expect when the circuit the power given to which they wished to measure had very much self-induction, that the wattmeter would give an answer far too high. In the wattmeter used at the Central Institution, the self-induction of the fine-wire circuit was made very small in the way just indicated, the resistance of the suspended coil having only $\frac{1}{150}$th of the value of that of the non-inductive stationary coil, but still the watts given to the primary as measured by the wattmeter were 200 per cent. too large when the secondary circuit was open.

Captain CARDEW said: He thought Mr. Kapp's paper would be generally considered a valuable addition to the rather meagre information which at present they had on the subject. The chief theoretical novelty in this paper was the method given of making allowance for the power lost in heating iron core, the difficulty of which was that this loss of power affected to some extent the angles of lag, and unless they could allow for this the electrical power supplied could not be exactly computed except, perhaps, by watt-meter. He did not feel quite happy about Mr. Kapp's solution. The assumption was that hysteresis produced an inductive effect always additive to that in the secondary coil, and if there were a true molecular friction this might be the case; but surely this was not the whole of the molecular forces, and the molecular forces as a whole opposed magnetisation and helped demagnetisation, while the friction alone opposed change of magnetisation. His ideas were probably very crude; but he looked upon a molecule of iron under cyclic changes of magnetisation as a straight spring bent first one way and then the other out of its natural position. When you bent it, there was opposing force; most of the energy was stored up and given out as the spring returned, but some was lost in friction. He was going to show his idea of the curve of magnetisation. Although the molecular resistance, apart from friction, might not expend energy, it might alter the curves and lags at different points. As it was the rate of change of magnetisation as a whole, which affected the secondary current, he did not see how they were to separate the frictional effect from the force opposing magnetisation and helping demagnetisation, which at one part of the curve acts with the friction, and, with the secondary current to oppose magnetisation, and, at another part acts against it. The risk to life from the use of the alternate transformer system had been the subject of anxious consideration, and apart from any question

Digitized by Google

of Government interference ; it was certain that any serious accident would materially check the progress of the system. The risk could not be considered chimerical. They had in a transformer two conductors laid in close contact with each other, and with an iron core, and they were necessarily thinly insulated. One of these conductors might acquire at times any potential difference up to 2,000 or up to 2,400 volts over the other. He need not point out to this meeting that in the primary circuit, taken as a whole, there was certain to be a resultant leak. The other conductor had also its resultant leak, and this was likely to offer a resistance of not many thousand ohms. They had here what would be recognised by all who had worked much as cables and condensers, conditions favourable to an eventual breakdowns Seeing the obvious importance of some safeguard, he had waited in vain for its being brought forward, and he eventually attempted a solution himself, with a result they saw here—[pointing to an exhibit]. This iron box was a trap for leakage. This piece of aluminium foil—not platinum, as Mr. Kapp said—the lightest, not the heaviest metal—is what they might call the bait. It consisted of two round discs, separated by a narrower portion. This was laid flat in a shallow depression in the bottom of the box, which prevented any lateral displacement. There was also an insulated disc, which was just over the aluminium, and it was connected to a piece of very fine wire, which supported a spring. The box was connected to earth. The distance of the insulated disc could be adjusted by means of a screw. There was also a little disc which told them the distance at which the insulated disc was above the aluminium foil. This insulated disc was connected to any point on the secondary circuit through that piece of fine wire. Should the secondary circuit ever acquire a potential differing from the earth by more than whatever volts the safety device was set for—anything from 500 upwards—the aluminium foil was drawn up by the ordinary static attraction until it was in contact with the disc attached to the fine wire. The instant it was in contact with the disc of course it was repelled, but while in contact it had completed the circuit, and an arc would follow it, which, of course, quite instantaneously fuses the fine wire. As soon as the fine wire was fused, down came that spring and short-circuited the primary circuit, causing the double pole cut-outs to operate. He had here one of those little foils which had been used several times over. It was so little injured that it had been used again and again. It had stood an alternating potential of 2,400 volts. Prof. Ayrton suggested these things were not necessary, because it was so easy to connect a secondary circuit to earth. That, of course, had occurred to a great many people. If they connected the secondary circuit to earth, at any rate it was all right for the customer. But putting the secondary circuit to earth insured that, as far as the secondary circuit went, there was no insulation, and consequently it practically did very much increase the strain on the insulation between the primary and the secondary circuit. Mr. Kapp described another device which had the same objects ; he would only say, as a customer, he should be quite satisfied with it. As a maker of transformers, he should take it as a boon, because he should expect there would be a considerable demand for transformers. As a supplier of light, he should rather object to it.

Mr. A. Bernstein said that in addition to the very excellent paper of Mr. Kapp, and the interesting remarks of Mr. Mackenzie, they had another paper that evening by Prof. Ayrton, "On the theory of Secondary Generators," for which they were all very thankful. Under these circumstances, there was rather an *embarras des richesses* of questions upon which one might be induced to enter. He would confine himself to a very few, and those only in which he felt naturally most interested. One of these questions was that of putting transformers either in series or in parallel. Mr. Kapp had already said that where light was to be distributed from stations over a very large area it might be advantageous to put the transformers in series ; but in relation to that he should like to call attention to some very important facts. In a system of transformers, where they used high-tension alternating currents, the question of insulation became a very serious one, as they had just heard from Captain Cardew. If they used transformers in parallel, they were obliged to use two main conductors between which there was a very high difference of potential, say 2,000 volts, and they were, further, obliged to put them very close to each other in order to prevent induction on other wires. This made the insulation exceedingly difficult. Where they had transformers in series they only had the highest difference of potential at the dynamo end of the circuit, and they reduced the difference of potential constantly on their line, so that the mean difference of potential was only one half as much, and from the theoretical point of view one would say the tendency to produce a leak would only be a quarter as large. This, of course, was a very serious matter in the insulation of these conductors, but in addition to this the matter became of far more importance, even in the transformer itself. In a transformer on a parallel system they had the same mean difference of potential of 2,000 volts between the ends of the coil, and as they could not use very heavy insulation in these coils if they wanted to have an efficient transformer, there was only a certain liability of leakage taking place. In a series transformer this difference of potential might be reduced to 50 volts or 100 volts, or just according to circumstances, and that enormously reduced the tendency to produce any leakage. Those were two very important advantages which the series system had over the parallel system, and they were so very important, as he said before, because the question of insulation in a transformer system was one which offered a good deal of difficulty. There was another question which he should like to ask Mr. Kapp. They had been told repeatedly, although there was hardly any distinct statement made in regard to the matter, that although the efficiency of the transformer is very high when the maximum amount of power is used, it is considerably reduced when the number of lights is decreased. He did not see why it should be so very considerably reduced, but the statement had been made. Anyhow he was inclined to think in this respect, too, the series transformer would offer an advantage over the parallel transformer. That was a matter on which he would be glad to have some information from Mr. Kapp in his reply. He would now turn to another point. That was the device to prevent the current going from the primary into the secondary. First of all they would see at once that where there was a tendency to short-circuit the primary with two thousand volts, there was a tendency to heating. That destroyed the insulating material between the primary and the secondary, and there was a leak. The device of Mr. Kent might work very well, but it might, at the same time, do a great deal of harm if proper precautions was not taken. There was such a thing as leading an electric current into temptation ; that is to say, if they gave an electric current a chance to go to the ground and find another way it would surely do so. He would illustrate that by an example. There were in the United States a very large number of arc light circuits several miles in length of overhead wire. After these had been introduced, it was considered advisable to put lightning arresters on these circuits, and the curious observation was made that while formerly it was a rare case that the lightning should take its way through the wire, as soon as the lightning arresters were put on it occurred very frequently. Those lightning arresters, in fact, acted, to a certain extent, as lightning inducers, and the remedy was only found by very much increasing the distance between the plates, so as to give the current from the lightning more resistance. In using such devices as that of Mr. Kent proper precautions must be taken not to give the current a chance to leak from the primary into the metal plate, and from there into the earth. Prof. Ayrton had mentioned another device which consisted in connecting the secondary to earth. With regard to these matters, he should like to mention something on behalf of Prof. Forbes, as that gentleman was not then present. When he first showed some members of this society his contact plug used in his system of series lighting, with which he supposed they were sufficiently familiar, Prof. Forbes at once made the remark that this contact plug would work exceedingly well to protect the secondary line by making a connection to earth, because the principle of the contact plug was this:—That as long as the difference of potential between the line and the earth was a normal one, there was hardly any perceptible current going away, and it might be made very high, 2,000 ohms or 5,000 ohms, if they wished ; but whenever this difference of potential increased, which would be the cause of the leak from the primary to the secondary, then that contact would at once make a short circuit. That, he thought, was a very ingenious idea of Prof. Forbes, and he considered it preferable to seeing it dragged to earth as suggested by Prof. Ayrton. He only wished to add in regard to Mr. Mackenzie's paper that he fully agreed in one of the observations which that gentleman made, and that was that they should never put the electric light on to gas fittings, especially in systems in which the high-tension current was used. It was an enormous mistake to do so, and it always led to faults. In America, to his knowledge, it was distinctly prohibited wherever high-tension currents came into play. He heard from some gentlemen connected with the Edison Company that, even with low-tension currents, they did not like it. He himself thought it was an altogether bad practice. It was a practice which was only resorted to to make things cheap, but it was certainly one which ought to be abandoned.

Mr. Atkinson (of Halifax) said the few remarks that he would make referred principally to Mr. Mackenzie's paper. Mr. Mackenzie said that the great improvement of the last year or so had been the introduction of iron into the armature. He quite agreed with Mr. Mackenzie that the introduction of iron had been a great advance, but the mistake seemed to have been made of attempting to work the iron to the same degree of saturation as had been attempted in direct-current machines. The builders of the multipolar disc dynamos had found by experience that with more than six poles, at all events, there was great difficulty in keeping down the heating of the iron in the armature, however well it might be laminated. A short time ago he roughly made a calculation (taking that as a basis) of how many lines of force they might take in an alternate current machine without danger of heating from magnetic hysteresis. Thus assuming that a six-pole machine running at 600 revolutions with (taking Mr. Kapp's system of figures) about fourteen lines to the square inch, which he believed was about the maximum, they could work a machine of that size and speed, then with a sixteen-pole alternating machine at the same speed, and assuming there to be no greater hysteresis from viscosity, they could not use more than about nine lines to the square inch to produce the same amount of heat. That pointed at once to a considerable reduction in the density of magnetic lines to be used in alternate current machines. In the machine which Mr. Mackenzie had described he placed alternately coils on primary circuits separately excited, and similar coils differently wound formed an alternating circuit. Now it appeared to himself that on working this there would be produced equally in both of those coils an alternating electromotive force, and therefore unless the machine was excited by a series dynamo, or some dynamo with considerable self-induction about it, there would be a very large alternation in the exciting circuit, and as, generally speaking, continuous-current dynamos were not constructed to stand that, it would produce rather a curious effect. He did not know whether Mr. Mackenzie had practically discovered that, or whether he had had any practical difficulty from that fact. He (the speaker) had brought there (it was hung upon the wall) a photograph of the Connaught dynamo, designed by Mr. Kapp, and constructed by Messrs. Goolden and Co., for producing alternate currents, which had iron in the armature. That particular machine was for 2,000 volts, 30 amperes, and 600 revolutions, and weighed 2½ tons, which was about 90lb. to the unit, which was a pretty fair result. The armature was a large hub of cast iron or steel, on the rim of which was wound iron tape. On the other side of that was carried an iron wire—that is, because the magnets came over the

Digitized by Google

top so as to laminate in all directions at right angles to the lines of the core, which was all securely riveted through, and they would see, coming through the hole there, driving spurs round the wire. The magnet ring was 40in. in diameter. There were 16 pairs of poles, and the speed at which it ran was 600 revolutions. That the thing was mechanically good was shown by this fact, that when it was running at about 1,500 volts, and at its full speed, it was accidentally short-circuited, which pulled up the engine and gave the engine a considerable shock; but there was no damage done to the armature, and no wire shifted in the slightest degree. That was a pretty severe test, because the armature had a very low self-induction. Mr. Kingdon called attention to his machine as possessing this advantage, that he could attach those inductors direct to the fly-wheel of an engine. He himself did not know what Mr. Mackenzie's experience with the owners of engines was, but he thought for one owner whom he would get to allow him to attach this kind of thing to the fly-wheel he would get about a hundred who would put on a pulley and would drive a machine that was going at another speed and could be conveniently put at any place they required. Moreover, he himself admitted the advantage of using a larger number of small machines rather than one very large machine, which, in the case of a breakdown, would totally collapse. Further, a good deal had been made of the point that in machines of the class shown on the wall, what they might term the armature circuit (that is, the circuit which produced the current) was not moving, and that, therefore, the circuits might be coupled in parallel or series, as the case might be. He did not think anybody would attempt to alter the coupling of a machine of that kind giving 2,000 volts while it was running. Generally speaking it was only for experimental purposes that a machine of that kind was required. People knew beforehand what they wanted, and they ordered it, and having got a machine to do the work they required, they did not want to alter it when it was running, so that he thought there was really very little upon that point. The only other point he would refer to was the remark of Prof. Ayrton as to the series compound-winding of transformers. He understood Prof. Ayrton to admit that he had not gone very far into the subject. He himself had devoted some little time to consider it. He regretted that he could only speak now from memory. He had come to the conclusion that somewhere or other there was a nigger in it. He could not see how the result is to be produced. In the diagram Prof. Ayrton gave, if he did not misunderstand that gentleman's meaning, he showed a coil placed in parallel with the main coil, and drew the analogy with a compound-wound dynamo. Now, it seemed they could not raise the volts on the terminals by putting one coil parallel with another unless that other coil was going to supply the whole circuit; that was to say, if that coil would produce more volts than the other coil, well, it would at once begin to work back through the other coil. Perhaps, however, he misunderstood Prof. Ayrton; but he was inclined to think from having considered it rather carefully that the compound winding of transformers could not be done.

Prof. AYRTON (describing on the blackboard) said that if they put two cells in parallel without one having higher volts than the other they got a higher difference of potential at the terminals; it was the simplest experiment in the world.

Mr. ATKINSON said that result was only produced by reducing the output of the original cell—that is to say, practically substituting the second cell for the original one, and if the original one was still doing its same work the electromotive force at the terminals of that cell would remain as before.

Prof. FLEMING said that he should like to describe some experiments that he made in 1885 in a couple of Zipernowski transformers, which were brought over and exhibited at the Inventions Exhibition. In that year Mr. Zipernowski brought over two of his now well-known lifebuoy-shaped transformers, and he placed them in the Inventions Exhibition, and he took the opportunity to make some experiments upon those transformers. He might mention that the transformers were wound in order to be arranged in parallel, and that they were worked from a self-exciting alternating current machine at some distance away, and in order to give the opportunity of seeing how this system adapted itself to the transmission of energy over great distances they placed the alternate current machine as far apart from the transformers as convenience would permit, and he believed that those transformers were a thousand feet away from the alternate current machine. Each of those transformers was intended to work a full load of two hundred 16-candle lamps, and they were connected by a No. 10 wire with the machine. He might mention that the primary current was operated by an electromotive force of about 1,000 volts. At that time Dr. Hopkinson had just drawn attention to some possible danger that might result from electrostatic capacity on the part of the transformers used, and it immediately occurred to the speaker, as it did to others at the same time, that that difficulty might be remedied or diminished by connecting the secondary circuit to the earth, and in these transformers exhibited in 1885 the secondary circuit was connected to an earth-plate. On mentioning this Prof. Elihu Thomson, of America, wrote to one of the technical journals to say that he had suggested that method before, and thereupon Profs. Ayrton and Perry wrote also to the same journal to say that they had suggested it before Prof. Elihu Thomson, and there the matter rested. He might also mention as an interesting fact in connection with these transformers that Mr. Zipernowski had arranged a method of self-regulation which was not very unlike that which had been sketched on the board by Prof. Ayrton. He could not for the moment trust his memory for the exact details of the method, but it would be found in one of Mr. Zipernowski's specifications for the year 1885. The principle of that method was the use of an additional transformer, which was so arranged that when the terminal volts at the main transformers were lowered this additional transformer raised them again, or tended to raise them again, to the normal value.

Prof. AYRTON said that he had mentioned the names of Gaulard and Gibbs, but he expected that it was Zipernowski. He should like to know whether it answered fairly satisfactorily.

Prof. FLEMING was understood to reply that he thought it did. He went on to say that then their attention was naturally directed to some method of determining the efficiencies of these transformers. They knew at the time of the quadrant electrometer method, but they had not got a quadrant electrometer. Mr. Zipernowski had brought over with him a couple of large wattmeters which he had constructed, from which they thought it might be possible to get some results tolerably trustworthy. The wattmeters were like the Siemens wattmeters, but they were made very large, and the intention was to make the induction of the fine wire as small as it could possibly be made. For that purpose the movable frames were made very large, and the whole of the fine wire resistance was not put into the movable frame. Fine wire resistances were placed outside the movable frame in the form of a non-inductive resistance in series with it; and the actual moving frame or the voltmeter part of the wattmeter consisted of a comparatively few number of turns forming a large rectangular frame, and if he recollected rightly these wattmeters stood some 2ft. high. In these instruments in the position in which the reading was taken there was no induction between the fine wire and thick wire circuits. Provided with a couple of these instruments, one of them placed in the primary circuit and the other in the secondary circuit, they made some measurements which they hoped would give them something approximating to the efficiency of the transformers at various lamp loads. [The results obtained were shown in a diagram exhibited.] It was obvious, of course, from what Prof. Ayrton had said, that those numbers could not be correct. But it would be very interesting now with the apparatus designed and worked by Prof. Ayrton to ascertain how far readings taken with the wattmeter built on this plan did give discrepancies between the real percentage of the transformer and that obtained in this way. It was very important that attention should be paid in connection with transformers to the question of the actual magnetic lag. There was no question that magnetic lag was a reality, and that there was a lagging behind in the time in which iron reached its maximum magnetisation as compared with the time at which the magnetising force came to a maximum. It followed from that that they would have to modify the method of treating the magnetic resistance of magnetic circuits in a manner analogous to that in which they had to modify the resistance of electric circuits when they were dealing with alternate electromotive force. They knew perfectly well that they had to bear in mind—and he would impress this upon beginners—that they did not and could not obtain the average current in a circuit working under an alternating impressed electromotive force by dividing the average value of the impressed electromotive force by the resistance of that circuit. But they would have to consider the resistance instead of that quality, which had been properly called by Mr. Oliver Heaviside the impedance. The impedance was a quantity which took into account the quality of the conductor, in virtue of which there was a lag of current behind the electromotive force; therefore, in dealing with the question of magnetisation, it would follow that in the case of magnetic lag in magnetic circuits they must substitute for magnetic resistance a quantity which might be called the magnetic impedance of the circuit. The theory of the transformer was in one respect simpler than that of the dynamo, because they had no air gap to consider, and they had in properly designed transformers no waste field. The undetermined quantity which appeared in all the theoretical investigations at present published on the theory of the transformer was the magnetic resistance term; and it was necessary that special experiments should be made in order to ascertain what were the values of the magnetic resistance corresponding to the same magnetising forces only operating under different periodicities. The experiments which he should like to see carried out on this subject would be the effort to obtain what might be called the permeability curve of iron under alternating magnetising forces when they were working with the same average magnetising force, but operated at very different periodicities. With regard to the question of safety it could not be doubted that in the course of time very many different devices would be designed for attaining security and preventing the electromotive force from the primary circuit getting into the secondary circuit. It would no doubt be possible to arrange something on a plan which would be tolerably simple, and yet, perhaps, work effectively.

The speaker concluded by sketching on the blackboard a form of automatic cut-out for separating off the secondary circuit in case of a rise of E.M.F. in the secondary much above its normal amount.

Prof. AYRTON said that he now recollected that there was a Zipernowski wattmeter that he had used. It was made exactly in the way Prof. Fleming described, and it gave an error of 300 per cent. The greater part of the resistance was non-inductive. There was a separate resistance box; the fine wire coil was fairly large, with comparatively few convolutions.

Mr. CROMPTON said he should like to say a great deal upon this subject were it not for the lateness of the hour. He would not go in much for mathematics in what he was going to say, but he thought his remarks would interest some members, because he proposed to tackle this question from a commercial point of view. In order to do that he was proposing to catechise Mr. Mackenzie on two or three most important points, and he should be much obliged if that gentleman would come prepared to answer those points at the next meeting. Mr. Mackenzie had been the engineer to the Grosvenor Gallery installation, and had had close connection with some of the large commercial enterprises that had been using alternate transformers, and he would like to know if he would give to the society certain information as to the actual efficiency of this system. They had heard a great deal of the efficiency of transformers, and they had heard a great deal of the efficiency of dynamos and the steam engines that drove them. He himself was prepared to give the efficiency of other systems

Digitized by Google

right out, from the coal bills to the electricity sold to the consumers, and he wanted Mr. Mackenzie to do the same. Then he proposed to compare the two systems together, and then they would begin to know what it all meant, and whether these high efficiencies claimed for these transformers, when the transformers were worked to their full capacity, could actually be measured when they were worked at very low capacity. That was the most important part of the whole subject, and it really affected them commercially more than anything else.

The CHAIRMAN announced that the discussion would be continued on Thursday, the 23rd inst., and the proceedings terminated.

INSTITUTION OF MECHANICAL ENGINEERS.

DISCUSSION ON MR. GEIPEL'S PAPER, "ON THE POSITION AND PROSPECTS OF ELECTRICITY AS APPLIED TO ENGINEERING."

Mr. J. FEARFIELD, Stapleford, Nottinghamshire, opened the discussion. He said that the question of electrical engineering was coming up before the whole of the members of the Institution as the coming trade of this country. The author said that "were it not for the cost of the dynamos and motors electricity would supersede, to a great extent, the use of belts and shafting," and he (the speaker) should like to tack at the end of that "were it not for the cost of the brushes and commutators and the armatures." He had put several dynamos down by one of the best makers in England, and he found with some ten or eleven now running that, even with good ordinary engine drivers, who had been fairly trained to the work—not electrically trained—there was not the knowledge which it was desirable to have. The armatures were often wearing down. He had four of them running in his own works and eight or nine in other works, and he found that the repair of armatures ranged from £4 up to £7 and £8, and in one instance £10 per annum, the armature only costing £18 in the first instance; and it was caused by the wearing down of the phosphor-bronze commutator, which, if oiled too much, forced from the brushes, and the electrical current cut the barrel of the commutator irregularly; and, therefore, they were forced to put it in again and true it up, or else they would find the engine-driver run it dry, and the brushes, whether they were wire or split plate brushes, cut it at once, and the copper dust got inside their work. When they sent the armature to be repaired they found the insulation was gone in several sections, and it had to be rewound. He was merely mentioning this fact from his own experience, for, unfortunately, he had had to put several of these armatures down, and this was an item of expense; and this applied not only to transmission of power but also to electric lighting. With regard to the cost of the electric light, he had had a good deal to do with electrical transmission and with electric lighting, and he found that it varied very much. In a small plant he had put down it could not be kept, under the most favourable conditions, under seven shillings per thousand cubic feet. The Nottingham Corporation supplied them with gas at a distance of nearly eight miles from Nottingham for 2s. 4d. per thousand cubic feet, and with the electric light, extending over a period of four years, it had practically cost them 2s. 1d. per thousand cubic feet. That was with an equal light. Now, some people expected to get from the electric light ten times the amount of light that they got from gas, but they placed no value whatever upon the consideration that the electric light gave them a purer light than gas, a far better atmosphere and no dirt. In one case, where there were over 90 girls at work, the factory inspector congratulated his father upon having the electric light put in because of the difference it made in the health of the girls. Then the person for whom he had done this work congratulated them upon the absence of dust upon his lace, and therefore a saving from the cost of the spoilt stock. In the almost immediate future engineers would have to deal with the electric light and the electric transmission question together. With regard to their being easily fixed and as to conductors, there was a party given at a place close to their works, and they wanted a few lights up in front of their house. He sent two men—one was a fitter and the other was a man who attended to the dynamos—to do the work. They were back again at the works in two hours, having placed twenty-four lights in the gardens in front of the house. The lights worked for two nights, and they were taken down again in an hour and a-half. He drew attention to that point to show that the electric light could be fixed far easier than any other light.

The PRESIDENT: Would you kindly tell us what the cost of your gas was, and would you compare that with the cost of your electric light?

Mr. FEARFIELD said that where the Nottingham Corporation delivered—and they delivered on several radii within eight miles of their gas works, —they delivered at 2s. 4d. per thousand cubic feet. Compare that with one small installation that only drove 30 or 40 lights—in a factory which had steam in the boilers at 95lb. pressure day and night (Sundays included)—it would cost, including repairs, pretty nearly 7s. per thousand, and it would cost to put the same light in with gas 7s. per thousand cubic feet. In the most favourable installation of which he had any knowledge the electric light cost, in comparison with gas, about 2s. 1d. per thousand cubic feet.

The PRESIDENT: The same candle power?

Mr. FEARFIELD: Yes. For the same absolute light that I get scattered over those works I should have to pay 2s. 4d. per thousand, and I only pay by the electric light 2s. 1d. per thousand for the same light. In the other instance, that of the Limited Company, they pay an equivalent of nearly 7s. per thousand cubic feet. If they were to put gas on, to get the same amount of light, they would have to pay 7s. for it. In the one case the electric light cost something like 30 per cent. less than gas, cheap as it is; in the other case it costs about 300 per cent. more. It is simply a question of the size of the light; it is a question of the convenience of the engine, the convenience of the driving, and the size of the plant. In one case it is running 55, at the most 60, lamps of 16 candle-power, and in the other it is running 300 lamps of 18 to 20 candle-power. It is a 500-light installation really, but I never have more than 400 lights running at once.

The PRESIDENT: Are we to understand that you mean a larger installation costs you more than a smaller installation?

Mr. FEARFIELD: No, I beg your pardon; the larger the installation the less the cost will be.

The discussion was then adjourned until the following evening.

DISCUSSION RESUMED.

The discussion was resumed on Friday evening, when Mr. Carbutt occupied the chair.

Letters were read from Messrs. Henry Barcroft, A. P. Snell, Sydney F. Walker, A. S. Bolton, and Mr. Thomas Urquhart, of Borisogeluck, Russia.

Mr. SCHOOLBRED said that he quite agreed with Mr. Geipel that although electric lighting was a branch that had received by far the largest attention, in the approximate future the motive power would certainly receive great industrial application, and probably a very much larger amount of current would be used in that direction than in lighting, inasmuch as numbers of small industries would make use of such a cheap and cleanly mode of getting motor power throughout the entire day. Electric lighting had been produced on such a very small scale—in fact, an experimental scale—that it was out of reason to compare it with gas, which was produced on a scale hundreds and thousands of times larger than electricity; but he thought there was very little doubt that even gas engineers themselves would admit that with equal rates of production electricity was cheaper than gas. To his mind the future of electric lighting lay very much larger in the use of central station lines, which were just beginning at the present time. They would enormously reduce the cost of the supply of electricity. It stood to reason that where all the various establishments that were at present detached all over a town were concentrated in one central establishment the current could be produced at a very much cheaper rate. It appeared to him that in many cases, especially where public authorities supplied the current, they had no right to limit its use simply to lighting. Even commercially it would be found that the motor power would be largely used. He did not think it would be very long before people would discover that alternate currents in applications of that kind were not those which were suited for general use. Mr. Geipel had referred to the cost of the lighting at Messrs. Jaegers' sugar factory at Leith. He (Mr. Schoolbred) would refer to Messrs. Tait's sugar works in the east of London. There the installation was put up eight years ago. They began with arc lights, but eventually, when incandescent lighting came to the front, they adopted it, and they had now extinguished the whole of the gas lights in the place, although they were close to the Beckton Gas Work. They employed there 1,000 men, and so satisfied were they that electricity was cheaper than gas that they had used it in another establishment in Liverpool where they employ a similar number of men.

Mr. VOLK, of Brighton, said the mechanical engineers seemed to look upon electricity as though it was some formidable rival; but he wished they would regard it purely as a means of transmitting force from place to place. The manufacture of the dynamo and the motor was purely a mechanical undertaking. Electricity would run a heavy train up very steep gradients. The circuit of any given line would represent a number of beads on a string, circulating up one line and down the other. The carriages or beads would not all be taking the gradient at once, and the cars running down gave a certain amount of power to the line. There was practically an electrical balance maintained between all the cars on the track. His cars were hung on some little stirrup irons three or four inches clear of the roadway. There was no box or protection round them. The salt air and spray could flow straight under the car, and had free access to the motor. The motors had run from April, 1884, to the present time, and new brushes had only been put on them once. Those were only put in last year, so that the motors had run three years with one set of brushes. Where a motor was put into a box and the brushes were carefully attended to, the wear and tear would be nothing at all, and 10 per cent. would amply cover all depreciations, renewals and current repairs. He had taken the actual figures of his working expenses during the past four years, including gas, oil and waste. These items amounted to £430. 13s. 7d.; the repairs, the refacing the slides of the gas engine, and a little asbestos packing, amounted to £16. 7s. 5d.; the repairs to two dynamos and two motors, £64. 5s. 6d. After all, that money was spent in re-winding the armature, because one Bank Holiday a car was so heavily laden that it simply could not start at all, and the armature gave way. The working expenses were therefore only £32. These figures included everything that he had paid. He had put 10 per cent. per annum to the reserve and the average interest in addition was 13½ per cent. £509 had also been paid for damages. He took the mileage of the cars at 94,000 for the four years. That was only reckoning the mileage of one car, though two were run in the summer. The result was—gas, oil, and waste, 1·02d.; repairs to engines, ·04d.; repairs to dynamo and motors, ·16d.; wages, ·7d.; total, 2·1d. per car mile. That was not an imaginary reckoning up; it was the actual result of four years' working, and if any gentleman present was sufficiently interested in it and liked to bring down an accountant he would let him go through the books and show him all the vouchers. In his small way he thought he had fairly thrashed out the subject of electricity for light railways, and he hoped

Digitized by Google

that others would take up the matter of accumulator cars. His line was rather under a mile in length, with some very steep gradients on it, and at first he tried some differential clutch gear for climbing the gradients, one of which was 1 in 25. He found, however, that the cars could do without the gear, and therefore he had taken it off. At first he tried 4in. leather belting, but he had now adopted link belting, which he put on in 1884, and it was still running, and he hoped it would carry them through next summer. In speaking of the succession of cars passing up and down the line he did not mean that they should be sent without any conductors or drivers. Reasonable care must be taken to keep the cars a proper distance apart. He had found no difficulty in working them in parallel; each seemed to take its fair share of current. He had only had three working at a time, and so long as sufficient care was taken they were perfectly under control. The driver would control the speed of the car.

Mr. Holroyd Smith said the paper as a whole was merely a summary of what had been done nearly all the world over, and he thought the mechanical engineers met together in that Institution to assist one another in inquiring into the "why" and "how" of things. In Mr. Geipel's paper there was comparatively nothing of the "why" and "how" relative to the various matters he had mentioned. Mr. Geipel had mentioned in his paper Dr. Benardos' and Elihu Thomson's methods. Those who had had experience with welding would predict that Dr. Benardos' system of using the intense heat that was incident to an arc of electricity was out of the question for producing a solid weld. The surfaces of the plates were simply fused together, and it was not welding at all. He ventured (though he might be laughed at) to predict that Dr. Benardos' process of attempting to weld iron together by means of an arc of electricity would prove an absolute failure. On the contrary, the method adopted by Elihu Thomson in his works near Boston was one that had the elements of success in it. He held in his hand some specimens that had been produced by it. One was a fine wire of copper, which he himself saw welded, and it would be found very difficult to break it at the weld. He had also a bar of copper and a bar of iron welded by the same method. A large current of the electricity was brought to the clips that touched the iron, and then the ends of the iron were touched together, the current was turned on, and they gradually got warm, and reached fusing heat, and were then pressed together. It was therefore quite under the control of the operator how cool or how hot he made it before he pressed it. The result was consequently most satisfactory. That was an item with which they ought to credit their American brethren. He was much obliged to Mr. Volk for giving such a comprehensive statement as to the method on which he based his cost of haulage at Brighton. He wished to make a suggestion, and he hoped that the President would cause it to be made as public as possible, because it was one that all who were connected with the transmission of power and haulage had to face. What was wanted was that some basis for calculation of cost should be formulated. Statements were continually made about the cost per mile, but the figures varied so entirely that there must be some difference in the method by which they were arrived at. He thought considerable praise was due to those who had succeeded in getting dynamos used as motors that should maintain a constant speed under a variable load. The most remarkable example of them was the one now at work at the Bessbrook tramway. What was wanted was a motor that would do varying work under varying speeds. The power required to start a tram was very much greater than that required to keep it in motion. None of the cars at Blackpool were worked with worm-gearing, but he had used worm-gearing most successfully upon his Paris car. He had been told that a new process had been discovered and patented by an American whereby sodium was obtained at one-tenth of the usual cost. He would therefore point out that if sodium could be obtained at a very much lower rate the gilt would be taken off the gingerbread of those who were trying to obtain aluminium by some electrical action.

Dr. Hopkinson described his system of overhead conductors to be used for tramways or electric railways. The conductor was hung precisely as a telegraph wire was hung—from insulators overhead, those insulators being kept at approximately the same level. On the car, front and back, a contact piece was arranged transversely, so that the contact could be made with the wire overhead at any point of the width of the car. This arrangement had great conveniences, particularly with regard to going round curves and junctions, owing to the fact that contact could be made at any point laterally upon the car. It had been tested at Bessbrook, and its practicability had been proved. The author of the paper had spoken of the self-regulating property that the shunt-wound Victoria motor possessed—that of a constant potential. That was not a peculiarity of the Victoria dynamo, but was possessed by many others as well. The reason why more regulation was obtained by a shunt-wound motor was that in a generator of electricity, when the current passed in the armature, they had to give the brushes a lead, and the current then in the armature had the effect of diminishing the magnetic field, and that had to be compensated by what was well known as compound winding. In the case of the motor, in order to obtain a constant speed, they would require to diminish the magnetic field, and the brushes had not to have a positive but a negative lead; the current also was in a reverse direction to what it would be in the motor.

Sir James Douglas said the experience he had had had been only in one branch of the subject, namely, electric lighting. He did not agree with Mr. Holroyd Smith that but slow progress had been made in this country in the development of electrical engineering. It had, perhaps, not gone on very rapidly, but upon the whole not slowly. The lead in the new science was first taken in this country, and it had been fairly followed up, but perhaps commercial undertakings had not progressed as could have been wished. Installations which at first were considered to be perfect in a very short time fell back, and had been superseded in the wonderful development that was going on. In his own service when they were commencing it was thought that the machines were perfect, but very soon it was found that the dynamos were nowhere, and they had to be superseded. That was quite sufficient of itself to deter very rapid progress in installations and general lighting in a country like England. He well remembered when Faraday—who he was sure would have been delighted if he had been living now to witness the perfection that had been attained—saw the first dynamo at the premises of the Trinity House, Blackwall, in 1856, he exclaimed, "This was my child, but you have made a man of it." He was quite sure that if Faraday were now alive he would admit that his man had become a giant, and a very great one, too. His (Sir James Douglas's) work had been in the development of electric light for the service of the mariner, but up to the present it had only been employed in cases where oil and gas would not meet the requirements that were demanded. With electricity they had a power that appeared to go actually beyond what was required, and certainly the best installations, and one of the most important, was in a great measure due to Dr. Hopkinson. It satisfied every desire that could be conceived on the part of the mariner, who was perfectly satisfied with it. The only thing that he complained of was that at times he had too much light. He would not attempt to criticise the paper, but would only express his hope that the Institution would afford their meed of praise to the author for the information he had brought before them.

Mr. R. E. Crompton was sorry that the author and Mr. Holroyd Smith said that the practice on this side of the Atlantic was behind that in America. They could hardly admit that. All the great improvements that had taken place in dynamo machines had taken place in England; and certainly the machine which Dr. Hopkinson had designed and perfected was probably ahead of any other machine in the world. The machines made by Messrs. Siemens in London were far ahead of those made in Germany by the same firm. All those machines were far ahead of anything made in America (hear, hear). The largest dynamo in the world had been made by himself. Unlike the dynamo illustrated on the diagram, which had been designed to develop 400 horse-power but only developed 200, his dynamo had been designed to develop 500 horse-power, and had done it. Mr. Holroyd Smith had said he had great hopes of obtaining the cheap production of aluminium on account of the cheap production of sodium. He thought most chemists would support him in saying that a thing so difficult to dissociate from oxygen as sodium was not likely to be dissociated except at a great expense of fuel. The first time he used an electric furnace he could hardly believe that there had been anything more than an ordinary blacksmith's forge going on. Yet he had been having enormous temperatures, and had reduced a large ingot of aluminium bronze containing about 50 per cent. aluminium direct from the corundum. It was perfectly extraordinary that such intense metallurgical action should go on in such a confined space with such little heat to the surrounding bodies. He thought mechanical engineers were hardly aware of the enormous future there was before this new industry of electrical engineering. They hardly appreciated that it had got out of the regions of small telegraphic instruments. The plant his firm were using for turning out modern electrical appliances was more like that used for planing armour plates.

Mr. Cochrane said that, induced by the tempting promises of electricians, his firm had tried an apparatus at their works, which in the matter of development showed some progress beyond that which had been described up to the present time, seeing that it was self-contained, and bolts and gear were entirely disposed of. It was an apparatus capable of running at 10,000 revolutions per minute. It was balanced by a beautiful arrangement of turbines right and left, the steam being delivered into the centre of the apparatus at 50lb. or 53lb. pressure, and coming out at something like 2lb. or 3lb. pressure at the end of the work. That had only been at work a few weeks. He thought in the matter of development, with its splendid bearings and floating in oil—the chief part of the arrangement being to secure a constant supply of oil to the bearings—it was one of the prettiest little arrangements he had ever seen. The makers were Clarke, Chapman and Parsons, of Gateshead.

Mr. Thomas Gower said that his only connection with electrical science had been his practical connection with the Elieson system. On the North Metropolitan tramways they had been running in continuous heavy work for six months. They had covered about 30,000 car miles, and they had carried about 300,000 passengers or more, and in that time they had probably done heavier work than was done on any other electrical system in the United Kingdom. With regard to the cost per mile, he was not at present prepared to talk so glibly as he had heard a good many people. There was a considerable cost with regard to the accumulators; but he thought that electrical engineers would be very wrong if, because of the heavy cost of accumulators at present, they dismissed them as a means of cheap and effective traction. That would be the greatest possible mistake, because engines of the type he was referring to were capable of running on any properly laid line in the United Kingdom from any depot in which they could put a dynamo, a steam engine or a gas engine from that depot, and on those lines they could run those cars; whereas with any system of conductor they had to conquer the prejudices of local authorities and of central authorities. There was the greatest possible difficulty in getting any system adopted, whether overhead conductor or underhead conductor, except in tunnels or such places where they had the practical control of the line. With regard to accumulators, they had their vagaries; but he had come to this conclusion, that it was very largely a mechanical matter to manage accumulators well. In the six months they had been in daily work they had made considerable mechanical improvements in accumulators, entirely irrespective of any electrical knowledge, or of any particular electrical science. He found that very great advantages were to be gained by a different method of packing. The plates were practically screwed together immovably, and the spaces between the places to which these plates were bound were very small. Consequently when any swelling took place in the plates buckling was inevitable. They immediately began to make experiments with a view of letting the plates

Digitized by Google

be as free as possible. Since that time the principal accumulator makers in England had gone on in the same direction. The makers had announced to the world that they had been making accumulators on the wrong basis for many years, and they now saw the necessity of making a new type, and that was precisely in the same direction that his firm had discovered was necessary—that was to leave the plates in a free condition, so that there was scarcely any tendency to buckle, and the swelling showed in the direction which would do comparatively little harm. Accumulators should be very readily got at, and very frequently overlooked. He thought that accumulators would be found much more manageable, and that they could be managed with much less cost and with much less depreciation than had been hitherto supposed (hear, hear).

Mr. G. KAPP said that in the first place he wished to defend Mr. Geipel, if such a strong term might be used, against the attack which was made in a letter read at the beginning of the meeting. It would appear from this letter as if Mr. Geipel had not stated the correct facts with regard to the transmission of energy for a distance; but at the time when the paper was written he could not have stated the case as well as it really appeared. He referred to the transmission plant in the neighbourhood of Solothurn, a small town in Switzerland. The author said on page 12 of his paper that there was a turbine of 50 horse-power, and that this power was carried to Kriegstetten, a distance of five miles, and the efficiency was 70 per cent. A letter was read from Mr. Snell, in which he said it was nothing of the kind—that the turbine was 40 horse-power, not 50, and that the power delivered at the mill was 20 horse-power, and therefore the efficiency was only 50 per cent. That was a misconception. When they measured the commercial efficiency of a system of transmission, they did not begin by counting how much *could* the turbine give, but how much did it actually give. Then they compared that figure with the actual power that was received at the other end, not with the power that they might perhaps have, but with the power that they actually got. In this particular case the power put in at the turbine end stands to the power taken out at the other end in the ratio of 100 to 75, and not 100 to 70 as Mr. Geipel stated. But Mr. Geipel was on the right side. He wrote his paper in the summer, before the experiments were made. The first set of experiments were made with this machinery whilst it was still in the shop of the constructors, and there the conditions of actual work could only be got in a more or less imperfect way. They had to substitute artificial resistance for the resistance of the line; they could not foretell what might be the leakage of electricity along the line, which of course would lower the efficiency, and they could not so regularly load their motor. In England we were still ahead of every other nation. Even in Switzerland the designer of this plant is an Englishman. The makers thought it would be advisable to have a correct set of tests made, so they asked six gentlemen of very high standing in the mechanical world in Switzerland to go to this place and actually test it. They would appreciate the correctness of the result when he told them that one of the men on this committee was the inventor of the planimeter. A report was issued by them, and he received an advance proof some weeks ago. By that it appeared that the efficiency was not only 70 per cent., as stated by Mr. Geipel, but actually 75 per cent. Against the other objection that the power was smaller than stated, since the paper was written a 100 horse-power transmission plant had been started at Lucerne by the same designer. He would like to say a word or two upon the very mysterious apparatus which Mr. Holroyd Smith saw in America. That gentleman stated that somebody showed him a box; you put in a continuous high-tension current at one end, and you took out a continuous low-tension current at the other end. He, himself, had seen the same thing, only it was not in a box. It was at the Newcastle Exhibition. He had tested it himself, and he found the efficiency was something like 90 per cent. Since then he had followed up the question a little, and he had found that six or eight years ago M. Gramme, in Paris, did exactly the same thing; but instead of transferring high-tension currents into low-tension currents, he did it the other way about. M. Gramme's object was to telegraph over a long distance where the line has a greater resistance, and where in the ordinary way of telegraphing they would require a large number of cells and batteries to force the current over this long line. He had at hand a small number of fairly large cells, which gave him a large current, but the pressure was insufficient to telegraph to this distance. So he constructed a dynamo, or rather magneto-motor, the armature of which had two circuits, one of thin wire and the other of coarser wire. There were two commutators, and the primary battery was connected with the brushes of the coarse wire commutator. That made the armature revolve, and through the revolution of the armature a current was induced on the fine wire, and that was used for telegraphing on the lining. That was a very self-evident apparatus, there was nothing mysterious about it, and it was being advocated now for use in connection with the lighting of towns where the district is extended. They could have a small wire carrying the electricity from the station to the point of consumption, both for the safety of the people who use the light and for the convenience of having lamps independent of each other. The high-tension current was transformed into a low-tension current, which was distributed now in the same way as if it were generated on the spot (hear, hear). Dr. Hopkinson had told the Institute of his very ingenious system of avoiding the difficulty of switches and crossings in an overhead conductor on an electric tramway. This was really a very great difficulty. With an overhead wire, whether that be a slotted tube in which travelled a contact shuttle, or whether it be a wire upon which ran a small carriage, they could imagine that when they had to make a connection to right or left on the switches it was very difficult to get this little thing exactly to follow the way the carbon had to go. The troubles were so great that the system was practically limited to cases where there was a small line without any branches coming off it. In Scranton, in America, one of the earliest electric lines is working with an overhead conductor, and they had to put in a branch, and they found great trouble with the switches. Then Dr. Hopkinson invented his plan, where there was no need to alter any of the practical arrangements overhead, because the car came and picked up a current, right or left, just where it happened to be. He drew attention to a new system of underground conductors, where the same idea had been carried out. He saw it only last Saturday, and probably it was not yet known generally. It was the invention of Mr. Lineff, and it had been laid down on a small experimental line at the Chiswick depot of the Metropolitan line of tramways. To describe it briefly, it was Mr. Holroyd Smith's underground conductor improved in the way that Dr. Hopkinson improved the overhead conductor. In the Lineff system there was a central slot the same way as in that of Mr. Holroyd Smith. There was a cemented trough that ran all the way along. In the ordinary system of underground conductor there was a conductor put at the side of the slot in order not to be exposed to the dirt or water falling down, and the surface of the conductor must be bare all the way, because the contact rubbed on it all the way. Now the bare surface of the conductor was a disadvantage, because moisture collected on it, and it gave so much facility for surface leakage. In the Lineff system, instead of having a bare conductor there was a conductor which was insulated nearly the whole of its length. It was simply a gaspipe—a ¾in. gaspipe in that case—which was tarred over with some insulating compound. Into the gaspipe is placed, for making it a better conductor, a bare copper wire. The gaspipe was enwrapped with insulating material, and that was laid into cast-iron brackets, which were fixed to the same castings which support the slot. It might be asked, how could the electricity be conveyed to the car if the thing was all insulated? In a very simple way. At every three yards there was a T piece on the pipe, and into the T piece was screwed a kind of saddle. This saddle bends a little outwards, and from the car projects a knife at each end, within which is mounted a copper strip. The knife is bent so to come over the cable, and the copper strip terminates in an eyelet, and upon that was strung an ordinary steel cable. As the car travelled the surface of the cable touched one point after another, but never less than two. Naturally the cable would be used up very quickly when they rubbed it along at a speed of six or seven miles an hour through those cast-iron saddles—naturally the cable would be frayed out, and then the frayed ends might catch. To prevent that, upon the cable were strung a number of gunmetal beads. On these the cable travelled, and when they were worn out they could be replaced without having to take away the whole. The advantage of that was that they could have a crossing—that was one gaspipe conveying a current crossing another gaspipe, so that two cars could be run without interfering with one another. If this were a continuous conductor there would be a great difficulty on account of the conductors meeting (applause).

Mr. HENRY DAVEY took exception to the advocacy of the use of electricity for the purpose of working pumps in mines. Electricity as a distributor of power he fully believed would have a very wide application; but they must be careful not to falsely apply it, because they would only bring it into disrepute, and he was decidedly of opinion that this was a false application. Just let them examine the mechanical details of the arrangements for pumping water from mines by means of electricity. In the first place, he failed to see how it could possibly be applied to draining mines that had large quantities of water, such mines as were usually drained by means of surface or underground pumping engines. He imagined that the application which the author had in his mind was that of draining the dip or remote portions of mines by means of little portable pumps, and even then he thought that the application would be decidedly a false one. The usual method of working dip pumps was to take a little pipe off the rising main of the main pumping engine at the bottom of the shaft, carry it forwards, and apply a little direct acting hydraulic engine to work the pump. Nothing could be simpler than that, and nothing more effective. The efficiency must be much higher than by any electric system that they could possibly devise; and, besides that, these pumps very often became drowned and had to work under water. What would become of their motor? Then, again, in applying the motor to the pump they had a motor which usually ran at 1,100 revolutions per minute, and the pump should not be run at more than 30 or 40 revolutions per minute; and then they had to put in very complicated gearing to get down the speed, and in doing so the loss of efficiency must be very great indeed. He was perfectly convinced in his mind that any such application of electricity must in the end prove a practical failure. It struck him that where electricity would come in more extensively in use would be where power was to be transmitted for a very considerable distance, and there it did appear to possess in point of efficiency very decided advantages indeed, even judging from the limited experiments which had been already carried out. Then it afforded a ready means of utilising water power in districts which possessed that water power and which were remote from centres of industry. In that direction the transmission of power by electricity would come in better than any such limited application as that of applying it to the working of underground machinery in mines, which was at present done by very satisfactory and very practical machinery.

Mr. MORDEY said it had been remarked that the Victoria machine was not singular in being able to give a very constant speed with varying loads when supplied with constant pressure currents. But at the same time that he published that curve in the *Philosophical Magazine* his object was to draw attention to the fact—which was not then known, or at any rate was not then recognised, that simple shunt machines were capable of being made perfectly self-regulating. Only a few weeks before that the German Hopkinson (Dr. Fröhlich) had published a full investigation on the question of the regulation of motors, and although he had spoken of shunt motors, compound motors, and differential motors, he had entirely missed the point which was necessary to obtain constant speed regulation in shunt motors. He (Mr. Mordey) therefore published that curve simply to show that shunt motors would give constant speeds, and to point out that the right way to construct the motor was pretty much in the same way as the dynamo, to make a strong field and a weak armature magnetically. Up

Digitized by Google

to that time it had been generally recognised that motors should have a very strong armature magnetically, and a very small weak field was the right principle to use. He thought Mr. Holroyd Smith and Mr. Crompton were both right, although they differed from one another entirely as to the opinion about the practice in America. The practice was ahead in America in the sense that as soon as the Americans got hold of anything that would work they applied it. All the improvements in dynamos and in motors practically had been rejected on this side of the Atlantic; but in America they had applied electricity for lighting purposes and for power transmission to an almost infinitely greater extent than we had done on this side of the Atlantic, and particularly in this country. We seemed to make the improvements for the Americans to make money out of, for they took them and applied them. Since the application of the curve there had been made and used by one company in America over 5,000 motors. He did not think that all our motors put together since that time would amount to fifty, and he thought that mechanical engineers were a little to blame for that. He did not think they quite recognised the capability of electrical transmission, and they did not know what a tool electricity gave them. He hoped that paper would open the eyes of those doubtful upon this subject, as to the great advantages of electricity for purposes quite apart from lighting. As to the big Brush machine, he did not know that the machine only gave off half of what it was supposed to give. It was some time since he looked up the official test; but, as far as he knew, that machine gave rather more than was arranged for. The Cowles Company had ordered two or three machines of the same type, and the same size, and one larger, so that he did not think there could be any question as to the machine only being capable of doing half the work that it was supposed to do. There was no doubt that the electric light plant was now, and had been for some years, going out of the experimental stages, and from the fact mentioned by Mr. Geipel that a dynamo was running day and night for a couple of years, and only stopped on Sundays—because it was in Scotland, he supposed—there was no doubt that the plant was trustworthy.

Mr. ARTHUR SHIPPEY said there was no getting over the fact that electricity had just begun to make a very big headway, and that the one thing they wanted was cheap power; and he thought there was the means of giving them a cheap power, and that was by the utilisation of the waste gases of their coal mines, as there was no getting over the fact that waste gas could be used, and used very profitably too. On this question of the utilisation of fire-damp, he should quote from a paper in which it was stated that "it was very interesting to see fire-damp, the most dreaded enemy of miners, reduced by the genius of man to be his agent and servant, as has been done in Germany recently. The Wurm coal mines, near Aix-la-Chapelle, are particularly noted for the amount of fire-damp produced in them, and the minutest precautions had to be taken to prevent dangers that, notwithstanding this, were to be feared. Mr. Hilt, director of the mines, undertook the work. He constructed a line of piping that ran in front of all the centres of work, and ended in a main pipe connected at the surface with a powerful suction pump. But it was not enough to get rid of the noxious gas, it was necessary to utilise it, and so Mr. Hilt conceived the ingenious idea of causing the conduit to end in a gasometer. Upon isolating the latter, and placing wire gauzes here and there in the conduit, he was enabled to lead the gas to the furnace of two generators, and use it to help to heat them. "We are obtaining," says the director, "30,500 cubic feet of fire-damp, which distils 263 cubic feet of water. On uniting the fire-damp of all our exploitations we shall have 64 cubic feet per minute, and shall be able to distil 5,260 cubic feet of water per twenty-four hours. The utilisation of fire-damp thus stored may become advantageous from a commercial point of view. It may serve not only for gas motors but also well-constructed dynamos for lighting purposes." He had taken some pains to get some statistics on the question of fire-damp and waste gases in the Rhondda Valley, and taking the calculation of the quantity of power that ventilated the mines, and to get out the gas which existed there. To a very large extent it showed that there was nearly half a million of valuable fuel going to waste. If that was converted into steam for the purpose of use in some of the large machines of 500 horse-power, and the application of transformers, there was no difficulty in conveying that electricity, and generating it at the pit's mouth in a radius of 50 miles in England. There was no getting out of the fact that the colliery proprietors had every chance before them of lighting their mines by electricity, and lifting the coal, and in this way there was a great future for electrical engineers combined with mechanical engineers. There was a very great field for some of the engineers to construct a cheap and useful engine.

Mr. GEIPEL, in reply, said the paper spread over a large area and a wide field, and it was difficult to confine himself to any fixed point. Referring to the remarks of Mr. Fearfield, which had been answered to a great extent by other speakers, he complained that good engine drivers were not able to look after dynamos on account of the armatures scrubbing, the commutators wearing, and the brushes sparking. He thought Mr. Fearfield must have been particularly unfortunate in his experience, for he (Mr. Geipel) had had a good many installations under his control from time to time, and in very few cases were they able to get engineers to look after dynamos. They had got to be satisfied with men who oil shafting, with sugar boilers, as in the case of Messrs. Jager's dynamo, or other unskilled attendants. If anything happened or went wrong with Messrs. Jager's dynamo—it had not happened for two years—it would, of course, be necessary to call in experts, but as for oiling the bearings, adjusting the brushes, and keeping the dynamos clean, he did not think it should be requisite for engineers at all. That might also refer to motors equally well. There was no reason why a man should not oil his own motor and his own machine, and keep it running satisfactorily. Mr. Fearfield had also mentioned that the size of the installation had very much more to do with the cost of working than the time the installation was used per annum—that was to say, the amount of use they could get out of that installation. It did not do to take that too far, and to say that they could put down one lamp and an installation for that one lamp and work it as cheaply as a hundred. But, taking a reasonable average installation of 500 or 1,000 lamps, the cost of working that was very much more dependent upon the time that the installation was in use than upon the comparison in the size. He got out a curve, shown in the diagram, showing the cost of the light per hour, as compared with the number of hours of use per annum. Above a thousand hours it seemed to be fairly constant, but in going back to a hundred hours it rose very rapidly. Mr. Walker thought that five to ten per cent. was too much to lose in the mains. That depended very much upon the cost of the power that he was prepared to lose, and the cost of the conductors. It depended greatly upon the time in which the current was used and also upon the cost of copper and the cost of insulating that copper; in fact, in one of the diagrams it was shown how much potential it was economical to lose for the different cases. It did not follow that in all cases 5 to 10 per cent. might be lost; but that was not an unreasonable amount to lose, more especially in this country where coal was so cheap. Mr. Walker had also asked how a six horse-power motor did the work of a ten-horse engine. Well, the term ten-horse engine was merely nominal, in the first place; secondly, the torque of an engine (that was the twisting moment) did not increase with the load even if the load tended to pull up the engine. On the other hand, if they attempted to slow down a motor by putting on a brake they increased the torque. He did not mean to say they increased the horse-power developed, but they increased the amount of machinery that a motor in use was able to drive. By throwing on an extra printing machine it was possible for the engine to be drawn up or stopped from the mere fact that the engine was only capable of exerting a certain torque, whereas with a motor, if they tried to draw it up, it increased the torque and its power of overcoming the increased work for the time being. Mr. Schoolbred had asked if 200 volt lamps were obtainable. He was sorry to say that he had not been fortunate in coming across them, although Mr. Swan, who had had some experience in lamp manufacturing, saw no difficulty, or no reason, why they should not be made by improved manufacture. At the same time the curve was not drawn wholly to represent the resistance of the lamps themselves, it also embraced the potential used in the supply mains; 200 volts was quite a possible potential to use with existing lamps of 100 volts on the three-wire system. The question as to the joining the electric rails in America had been answered by Mr. Volk. There should be no difficulty in joining the rails in various methods. Even with fish-plates alone, without any other connection, he had known ordinary rails, connected by fish-plates, work quite satisfactorily provided that the rails did not carry the going and return currents, but were merely used as returns. Mr. Holroyd Smith would have preferred more details of the different applications mentioned in the paper along with the why and the how; but he (the author) thought this paper already sufficiently long, and would point out that his object had been to put before the mechanical engineers the actual practical position of electricity as an agent, as well as some of the chief uses to which it could and had been put, and not to enter into calculations of elaborate formulæ and mathematical theories, which he preferred to leave to others more capable of dealing with such than he was. Mr. Smith had misunderstood his remarks about the Americans. He did not wish to depreciate one iota the immense amount of good work done by our friends; what he meant to convey was that American engineers had taken advantage of what European scientists had discovered. He did not consider that Houston, or Brush, or those gentlemen he (Mr. Smith) had named, with the exception of Franklin, were scientists; they were practical engineers, or practical electricians, and had taken advantage of the discoveries of Faraday, Gramme, and other Europeans. He agreed with Mr. Smith that the samples of welding sent by Dr. Benardos were bad; but he thought Mr. Smith was premature in condemning this system altogether until further trials had been made. He (Mr. Geipel) thought that better results might be obtained by increasing the size of the arc, or by using more arcs than one so as to render the heating less local. He was not sufficiently practical to suggest that some flux might possibly facilitate the welding. Mr. Smith did not mention what items he had found omitted in the cost of working the tramway. He did not think his suggestion as to a basis for calculation of cost likely to be taken up seriously, the conditions of operating rail and tramways were too numerous and diverse; it was not a difficult calculation to arrive at the working cost of any railway in operation. He had not mentioned, as Dr. Hopkinson seemed to imagine, that self-regulation was peculiar to a Victoria motor; on the contrary, his statement was that *an ordinary* shunt-wound motor was self-regulating. He bore out Mr. Mordey's remarks as to the "Brush Colossus Machine," and thought it unlikely, if Mr. Crompton's remarks were true, that Messrs. Cowles would have since entrusted additional orders for similar dynamos to Brush, as he understood was the case. Mr. Crompton had called attention to what he thought was a weakness of the shaft of this dynamo, but he had omitted to inquire into the question of speed. He thought such details tolerably safe in the hands of Brush. Regarding Parsons' generator, he understood that it consumed upwards of 60lb. of steam per horse-power-hour, and although the compactness of the apparatus rendered it suitable in some cases, yet engines could be obtained to work with less than half that amount of steam. Mr. Davey was wrong in suggesting that he (the author) had in his mind little portable pumps; indeed, he had already tendered under guarantee for several large plants. One was for pumping 500 gallons per minute to a height of 200 fathoms, and he saw no difficulty in doing the work. He did not agree that the direct acting hydraulic pump *must* be more efficient. Did Mr. Davey calculate the loss by friction in the pipes and in bends as well as the loss due to the compression of air, which always found its way into hydraulic pipes in smaller or larger quan-

Digitized by Google

tities? It was difficult to get at the efficiency of hydraulic pumping; at any rate, it was easier to test the efficiency of electricity. Speaking of efficiency, he could mention a case of a colliery in Scotland where they had put in hydraulic plant; it was found that the stroke at the pump was about two-thirds of that at the receiver, although the ram at the engine was larger than that at the pump. He had pointed out to the proprietor of the colliery that this meant a loss of power; his reply was that the difference in stroke could easily be remedied by increasing the diameter of the ram at the engine. He hoped Mr. Davey appreciated, what this gentleman did not, viz., that the work exerted or delivered was an exact multiple of the area of the rams. There was no reason why motors should run at 1,100 revolutions; they could be supplied to run at 200 revolutions or less even, and an efficiency from engines to pump of 75 per cent. could be guaranteed. The author had hoped that some gentleman advocating compressed air would have joined in the discussion; as this was not the case he took it that the mechanical engineers admitted the claims he made in favour of electricity as to efficiency. With regard to the question asked by the President as to the working expenses of Messrs. Jager's installation, these figures were given to him by the Messrs. Jager themselves. The power required was merely calculated. The actual consumption of coal was also merely calculated. The dynamo was driven by a large engine, and it was driving other machinery. 3lb. per horse-power was a liberal calculation, but it was merely a calculation. He did not mean to say that in every case a saving could be made; in such a case as Messrs. Jager's the engine was running whether the dynamos were there or not; it cost nothing extra for firemen's wages, and the extra wear and tear of engine and boiler was neglected. The total number of lamp hours calculated from the gas consumption, and verified by subsequent calculations, was roughly 300,000, say 40,000 indicated horse-power-hours; in Leith ¼d. per horse-power-hour is a liberal allowance for all charges, including labour, fuel, oil, and depreciation on engine, boilers, &c. (all night work). 40,000 × ¼d. = £42, and substituting this for the £12, calculated by Messrs. Jager for coal, would reduce the yearly saving to £174. 0s. 4d., which included a liberal charge for horse-power.

The PRESIDENT, in proposing a vote of thanks to the author, said it was a fortunate thing that they had had a sort of *résumé* which had enabled them to take the subject in all its branches. They need not be ashamed of their electrical engineers—for they were going to find a large amount of work for the mechanical engineers in the future—but he should like any gentlemen to supply their secretary with any reliable data or facts as to the cost of lighting. He differed rather from Mr. Geipel, because his paper was very theoretical. There was nothing included for the driving of the engine, and the fireman and the firing of the boilers, and no labour whatever. The question ought to become, whether electric lighting of the future was driving the gas companies on to use the gas works for some other purpose. When he said it was far cheaper to make their coal into steam, and thereby create an electric current and have an electric light, the gas companies had this advantage—they had residuals, which any person burning his own coal did not get. The gas companies could afford to give them their gas for almost nothing if they could get a fair price for their residuals; and notwithstanding the improvements in electric light gas companies had gone on paying higher dividends ever since the electric light had come in. Electric light had forced everybody to go in for more light, and although nearly everybody was burning more gas the price of gas was reduced. But the important question was the cost of the electric light. What could you do compared with the cost of gas supposing you had 50, or 100, or 150 lights?

The proceedings then terminated.

THE LIGHTING OF THE CITY.

At the meeting of the City Commission of Sewers, held on Tuesday last, at which Mr. W. H. Pannell presided, the Streets Committee brought up a report submitting for adoption an amended arrangement with the Anglo-American Brush Electric Light Corporation for lighting a district of the City by means of electricity. The district to be lighted commenced from the front of the Royal Exchange, and comprised so much of the City as lies between the Poultry, Cheapside, St. Paul's, Ludgate-hill, and Fleet-street on the north, and Queen Victoria-street and the Embankment on the south.

Mr. J. C. BELL, in moving the adoption of the report, referred to the previous connection of the Commission with experiments in electric lighting in the City. In 1878 they tried the Jablochkoff system, at an expense of seven and a-half times the cost of gas, but, as far as they could judge, it failed. In 1881-82 they entered into contracts with three companies for experimentally lighting the City at the same time, to test which was the better system. The Brush Company charged for works, installations, and lighting in the district allotted them £1,410, or twice the cost of the gas there, but the light gave 15 times more illuminating power. The Lontin system cost £2,930, or four times the cost of gas, the illuminating power being 14½ times greater; and the Siemens system cost £3,720, or 3¾ times the cost of the gas in the district allotted them, the illuminating power being 13½ times greater. They afterwards entered into a contract with the Edison Company for lighting a part of the City with incandescent lights. None of these systems of experiments gave satisfaction. The terms of the present proposed contract with the Anglo-American Brush Company were double the price of gas in the same area—viz., £4,394, instead of £2,200—but they would get 32 times the amount of light. It was contemplated to use 196 arc lamps of 2,000 candle-power each, at a cost of £26 per annum each. The committee had selected the most frequented parts of the City for the experiment, but if it proved a success, there would be no difficulty in extending it throughout the City. He believed the contract was not only a fair one, but virtually a one-sided one in favour of the public. They had had complaints from many quarters of the insufficiency of the lighting in the City, but any increase in the number of gas lamps would be very expensive. Electric lighting would not only afford a greatly better light, but would minimise the risk of fire and tend to the protection of property. The cost would necessitate an increase of one-eighth of a penny in the pound on the ratable value of the City, of which about one-fifth of the whole area would be lighted by electricity. To those who had any experience of the atmosphere of the large establishments of the City, where hundreds of workpeople were employed—such as the printing offices—the advantages to health by the introduction of the electric light would be patent. While it was proposed to make a contract for a term of seven years, any failure of the company to observe its provisons would not only bring about its immediate cancelment and the forfeiture of the deposit of £1,000, but would inflict on the company the loss of their monopoly of private lighting, so that in their own interest the company would take care to have no failure. The whole of the installation was to be finished by October, 1889, but they hoped to have the City lighted street by street as the work progressed. The company would have, as far as the Commission could grant it, a monopoly of private electric lighting in the district, but they could not compel the inhabitants to use it, and it was, therefore, to their interests to make the charges as low as possible in order to secure orders and to compete with the gas supply. The same monopoly of lighting was now given to one gas company, with the result that the cost of public street lighting was decreased. In the present case it was estimated that each arc lamp in the streets would cost £40 per annum to the company, who would therefore lose £14 on each lamp; but they would bear this loss for the sake of the monopoly of private lighting. If the experiment proved successful they might go to other companies and get better terms, and if it were a failure they could fall back upon the gas, besides making the company pay for the failure. It had been suggested that the commission might undertake the work more economically and just as efficiently themselves, or, at all events, that they should have a right of pre-emption of the shares of the company, but as electric lighting was still in its infancy, he thought that at this period they had bettler let other people, who understood the work, do it. He contended that arc lighting was the proper mode for illuminating a city such as London, and observed that the contract contemplated the provision of shadowless lamps, and of glow lamps in the smaller streets. He believed that if the work was carried out as proposed the Commission would be entitled to the thanks of the community. At all events, they would be likely to bring the gas companies to their bearings. Even that small agitation had had the effect of reducing the price of gas by 6d. per 1,000, and he hoped that sooner or later the gigantic gas monopoly would be broken down. For these reasons he urged the Commission to adopt the report.

Mr. C. T. HARRIS, as an amendment, moved that the report should be referred back for further consideration. He argued that the present lighting of the City, as far as all practical purposes were concerned, was perfectly sufficient, and that anything further would be merely a luxury, for which the ratepayers should not be called upon to pay an increased tax. He objected to the report on four grounds—viz., because arc lighting was unsuitable for the purpose; because the illuminating power could not be adequately estimated, and was therefore enormously exaggerated; because the cost was prohibitory, and because he considered the terms of the contract open to grave criticism in the interests of the public. On these grounds he begged the Court to give the matter further consideration.

Mr. J. E. SLY observed that four or five years ago a great deal of money was spent by the Commission in experiments with the electric light. It was hardly for the Commission to contemplate lighting one portion of the City at the expense of the other. They had shown their desire for the light by the large sum of money they had spent in experiments. If they contemplated adopting the electric light it ought to be for the whole City. The Maxim-Weston Electric Light Company would supply the electric light to the whole City at £15,000 for the first cost, fitting, &c., and £3,875 a year for maintaining the light—800 lamps of 450 candle-power each being supplied. This would pay itself in two years. He asked them to reconsider the matter, so as to get it done in the cheapest way they could, and not to have a seven years' monopoly.

Mr. BRIDGMAN referred to the insufficient manner in which the City was lighted as compared with the Holborn District, and observed that he did not know a more dismal place than the neighbourhood of St. Paul's at night. The electric light had been adopted in New York, Brooklyn, Paris, Vienna, and some towns in England.

Mr. MORTON said he was strongly in favour of getting the electric light, but they did not want to be entrapped.

Mr. J. V. MOORE supported the amendment. He referred to the improvements which had taken place in gas lighting, and observed that gas was becoming a formidable rival to the electric light. A new lamp had been brought over from Berlin which gave a wonderful light at a consumption of only 12ft. of gas per hour. The Court could not, consistently with its duty, agree to the report, and it ought to be sent back for further consideration.

Mr. L. H. PHILLIPS and Mr. G. SHAW also supported the amendment, while Mr. Deputy SCOTT warmly advocated the adoption of the report.

After some further discussion the amendment was declared to be carried on a show of hands. A division was demanded, with the result that the amendment was carried by 36 to 17. The report was accordingly referred back for reconsideration.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

2,073. A. C. IWANOWSKI. London. An improved electric alarm apparatus. February 11, 1888.

2,088. J. G. GILCHRIST. Glasgow. Improvements in dynamo meters. February 11, 1888.

2,125. W. ROWBOTHAM. Manchester. An improved method of constructing and regulating arc lamps. February 11, 1888.

2,130. A. MUIRHEAD. London. Improvements relating to electric telegraphs. February 11, 1888.

2,170. F. W. WHITE. London. Improvements in bases and covers of switches or cut-outs used in electric lighting. February 13, 1888.

2,178. R. N. BOYD. London. Improvements in plates for secondary batteries. February 13, 1888.

2,179. M. WHEELER. London. Electric lights. February 13, 1888.

2,235. J. A. BRYCE. London. Improvements in or applicable to electric conductors. February 14, 1888.

2,239. J. T. MAYFIELD and J. T. TODMAN. London. An improved electrical door and window contact. February 14, 1888.

2,246. H. H. LAKE. London. Improvements relating to dynamo electric machines (R. Eickenmeyer, United States). February 14, 1888.

2,250. J. H. LINVILLE. London. Improvements in printing telegraphs. February 14, 1888.

2,251. A. GRAHAM. London. Improvements in switches for electric circuits. February 14, 1888.

2,259. H. MESTERN. London. Improvements in thermo-electric and furnace batteries. February 14, 1888.

2,304. S. SUDWORTH and E. L. BERRY. London. Improvements in fireproof "batten" lights for electrically lighting the stages of theatres and other similar buildings. February 15, 1888.

2,308. C. COERPER. London. Improvements relating to dynamo electric machines. February 15, 1888.

2,313. S. ZIANI DE FERRANTI. London. Improvements in dynamo electrical machines and apparatus used in connection therewith. February 15, 1888.

2,314. S. ZIANI DE FERRANTI. London. Improvements in electrical safety fuses. February 15, 1888.

2,315. S. ZIANI DE FERRANTI. London. Improvements in electrical mains. February 15, 1888.

2,316. S. ZIANI DE FERRANTI. London. Improvements in dynamo electrical machines and apparatus used in connection therewith. February 15, 1888.

2,368. M. BAILEY and J. WARNER. London. An improved method of manufacturing woven plates for secondary batteries. February 16, 1888.

2,369. J. ORME. London. An improved system of electrical or other signalling between signal cabin and driver and guard in charge of railway trains in motion or otherwise, and apparatus therefor. February 16, 1888.

COMPLETE SPECIFICATIONS ACCEPTED.

NOTE.—*All persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the dates in italics, give notice at the Patent Office in the prescribed form of such opposition.*

February 18, 1888.

2,598. T. P. HEWITT. Liverpool. Improvements in electric gaslighters. February 19, 1887.

5,096. G. KAPP. London. Improvements in dynamo-electric machinery. April 5, 1887.

5,485. J. HARGREAVES. Liverpool. Improvements in and connected with internal combustion thermo dynamic engines. April 15, 1887.

5,583. H. LIEPMANN (of the Liepmann Carbon Company, Limited). London. Improvements in galvanic batteries. April 16, 1887.

8,396. A. J. MARQUAND. London. Improvements in electrical apparatus for preventing corrosion or incrustation of steam boilers and other similar vessels, and for removing the incrustation when once formed. June 10, 1887.

100. H. H. LAKE. London. Improvements in and relating to apparatus for generating electricity (W. Humans, United States). January 3, 1888.

623. R. J. GULCHER, and the firm of J. PINTSCH. London. Improvements in thermo-electric elements and piles. January 14, 1888.

PATENTS SEALED.

LEGAL INTELLIGENCE.

The Faure Electric Accumulator Company (Limited) v. Philippart.

This case came on last Saturday in the Queen's Bench Division before Mr. Justice Hawkins.

The liquidator of the plaintiff company, which was being wound up, claimed to recover from Mr. Simon Philippart, a former director of the company, £70,459 for calls in respect of shares. The amount was made up as follows:—A first call of £1 made in November, 1882, on 22,532 ordinary shares of £10 each, standing in the name of the defendant, and forfeited in January, 1883; a second call of the same amount made on the same shares in December, 1882; two calls of £1 each on 2,000 ordinary shares standing in the joint names of defendant and Mr. E. L. Broubenge, together with interest at the rate of 10 per cent. in accordance with Articles of Association. The defendant denied his liability on a variety of grounds, asserting that the shares were held by him as trustee of a Belgian company entitled the Société La Force et la Lumière; and the plaintiff company, being well aware of the circumstances, had agreed that the shares should be forfeited, on the terms that neither defendant nor the Belgian company should be liable for either calls or interest. The Belgian company assisted, it was said, in promoting the Faure Company, and paid £50,000 in cash on the shares, and the arrangement was, it was contended, because of the large cash payment, that forfeiture should be a discharge of all liability. In regard to the second call the defence was that it was invalid, as it was made at a Board meeting, attended by only two directors instead of a quorum of three, as required by the Articles of Association. Furthermore, defendant contended that he had ceased to be liable because he had been bankrupt in France, and the liquidator had recognised the bankruptcy. On behalf of the plaintiffs, however, it was contended that defendant had not been discharged from liability, and it was denied that the bankruptcy had been recognised. As to the second call, it was said the quorum should, according to the Articles of Association, consist of three until otherwise determined, and in April, 1882, the Board resolved that two directors should form a quorum.

Mr. Channell, Q.C., and Mr. Grosvenor Woods appeared for the plaintiffs, and Mr. Finlay, Q.C., Mr. Henderson, and Mr. Merrick represented the defendant.

At the conclusion of the arguments his LORDSHIP said the matter was of some nicety, and he would take time to consider his judgment.

COMPANIES' MEETINGS & REPORTS.

The Brighton Electric Light Company.

We have been furnished with the following report:—

A meeting of the Brighton Electric Light Company's shareholders was held at the works of the Company on Saturday evening, and great satisfaction was expressed at the nature of the report for the past fifteen months.

The managing director, Mr. Arthur Wright, was congratulated on the successful manner in which he had conducted the Company's business. There had been a great increase in the consumption of electricity, and the plant had recently been considerably added to in order to still further cope with the business coming before the Company.

It was resolved that an expenditure of £3,000 be made on additional plant, and the shareholders expressed their willingness to take up a certain amount of new shares, but it was felt that an opportunity should be afforded to the residents of Brighton and Hove, and especially to the Company's customers, to take up a portion of the capital to be issued, and that after showing the result of a fair amount to be set aside for a reserve fund and a 5 per cent. dividend, many local investors would like to become shareholders.

On the motion of the CHAIRMAN, seconded by Mr. SMITHETT, the report and accounts were unanimously adopted.

A hearty vote of thanks was given to the Chairman and Directors of the Company, and in reply the CHAIRMAN mentioned that with the new plant at their disposal, the Company would be able to adopt the plan of continuous night and day service.

Mr. WRIGHT, in returning thanks, said that the plant and apparatus on the Company's premises were in the highest state of efficiency, and that from the gradual increase of business month by month he expected to be able to show even more satisfactory results next year.

Telegraph Construction and Maintenance Company.

Report of the Directors, to be submitted to the members at the twenty-fourth ordinary meeting to be held on Tuesday, the 28th inst., at one o'clock precisely:—

2. The accounts for the year show a net profit of £88,798. 6s. 7d. after charging the interest on the debentures. To this sum must be added £51,278. 4s. 3d. brought forward from last year, making a total of £140,076. 10s. 10d. From this amount is deducted the interim dividend of 5 per cent., paid July 19th, 1887, amounting to £22,410, leaving £117,666. 10s. 10d. to be dealt with. Of this sum the Directors propose to distribute a dividend of £1. 16s per share, absorbing £67,230, being at the rate of 15 per cent., and making, with the amount already paid a total dividend for the year of £2. 8s. per share, or 20 per cent., free of income-tax, leaving £50,436. 10s. 10d. to be carried forward to the next account.

3 During the past year a considerable amount of work has been carried out by the Company in the manufacture, laying, and repair of cables in various parts of the world. The gutta percha department has manufactured a length of over 8,000 miles of insulated telegraph wire, and the cable factories have been actively employed during the greater part of the year. The Company's steamships have made voyages to the Red Sea, (Perim, Assab, Massowah, &c.), to the Mediterranean (Gibraltar, Malta, Zante, &c.), and to the Atlantic (Lisbon, Halifax, Valentia, &c.). Cable repairs have also been executed in the North Sea and English Channel.

4. The Company's ss. "Kangaroo" has been chartered to the Italian Government for distilling purposes in the Red Sea.

5. The Company's steamship and the factories at East Greenwich and Wharf-road are in efficient working order.

6. The retiring Directors are Sir George Elliot, Bart., and Mr. Philip Rawson, who, being eligible, offer themselves for re-election.

7. The meeting will have to appoint auditors for the ensuing year. Mr. John Gane (Messrs. Gane and Jackson), and Mr. James Glegg (Messrs. Quilter, Welton and Co.), who retire, offer themselves for re-election.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 17th February were £4,420.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended February 17th, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,612.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended 15th February amounted to £3,310, as compared with £3,012 for the same period last year.

M. Eugène Martin has joined the Board of the Compagnie Continentale Edison.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 511.—Vol. XX. FRIDAY, MARCH 2, 1888. Price 4d.

NOTES.

The question of battery *versus* alternate-current transformers, which is now being so hotly contested, is dealt with this week in our leading article; but we may here note one or two points which space does not permit us to refer to at length. As to the alleged difficulty of running alternating machines in parallel, of course, it is understood that the difficulty only occurs when one machine has to be switched on to another already at work. If the alternations do not coincide, the leads will then be practically short-circuited while the two machines are getting into step. Messrs. Siemens, however, propose to get over this difficulty by a device which is, at least, good in theory. An electro-magnet is provided with two independent high-resistance coils; when the machines are running at the same speed they are each connected with one of these coils. The armature of the electro-magnet is held back by a spring which is so adjusted that it is only pulled down when the core is magnetised by the two coils simultaneously. The armature cannot fall, therefore, until the machines are working in unison, but immediately this has been attained the armature falls and closes the circuit of the second machine upon the mains.

Mr. Kapp said on Thursday evening that he should be unable to believe in the existence of magnetic lag until someone explained how its existence could be reconciled with the fact that a telephone can reproduce a high-pitched voice better than a low one. If Mr. Kapp will refer to *The Electrician* of August 12th, 1887, page 286, he will find an interesting account of the researches of MM. Grassman and Lahr upon this very point. The explanation arrived at by these authors is very simple, though not a little curious. It is that the male voice, though of lower pitch in the fundamental tones, yet contains harmonics far higher in the scale than those belonging to the female voice. In the soprano voice the whole of the tones belonging to a given note and its harmonics are comprised within a comparatively narrow range upon the diatonic scale. In transmission by telephone, therefore, these tones are all degraded to about the same extent, and the characteristic *timbre* of the voice does not much suffer. In the male voice, on the other hand, not only is the fundamental tone deeper, but the harmonics are higher, and the range covered by a single tone is far greater. Hence, some waves are much more retarded than others, and the final distortion is, or may be, so great that a man's voice is unintelligible where a girl's is perfectly clear. This explanation, of course, proves nothing for or against the existence of magnetic lag, because self-induction sufficiently accounts for the degradation effect; but, at the same time, it removes Mr. Kapp's objection as to the possible existence of magnetic lag.

The very beautiful experiment described by Prof. Perry on Thursday evening (see our report further on), by which it is possible to determine the nature and extent of the departure of an alternating current wave from the true sinusoidal form, is, of course, an exemplification of Fourier's theorem, by which any periodic function may be expressed as a sum of sines. This experiment has never been published hitherto, but Prof. Perry tells us that he has been accustomed to describe it to his pupils when explaining the theorem alluded to. The subject is one of considerable importance in the theory of alternating currents, and we may remind our readers that an elementary though complete exposition of the theorem has recently been given by Dr. Fleming in his "Notes on Alternate Currents" (*Electrician*, Nov. 18, 1887, page 28). The appreciation of this fact will remove the difficulty which found expression at the same meeting in understanding how it is that self-induction tends to smooth the irregularities of the current wave into the true sinusoidal form. For as Mr. Evershed (who argued to the contrary) correctly stated, the sine function is the only one which has a differential of the same character. Now, it is quite easy to see, physically, how the self-induced "ripples" due to the irregularities of the main current, being of similar shape but opposite sign, tend to cancel out with the very cause to which they are due, and leave, or tend to leave, a smooth curve.

The Bill of the United Telephone Company seeking powers for the erection of overhead wires within an area of 12 miles radius from the General Post Office is opposed by no less than 54 separate and distinct petitioners, who have lodged applications praying to be heard by counsel against the proposals. Amongst the petitioners are the Corporation of London, the Metropolitan Board of Works, twenty-one Local Authorities, fourteen private corporations, all the Water Companies (who object to the roads in the suburbs being dug up for the erection of posts), and, finally, all the Railway Companies in the metropolis, except the underground lines. It will thus be seen that the opposition is of a very formidable character. For our own part we are quite unable to understand in what way the present haphazard and irresponsible system can be considered

Digitized by Google

preferable to a recognised and systematic method of stringing wires under Parliamentary sanction and restrictions. Probably, however, many of the petitioners merely seek to amend the Bill in points of detail, and are not opposed to its general principles. We trust that this will prove to be the case; otherwise we fear that its fate is already sealed. Meanwhile, the enormous suburban populations of the metropolis are denied the advantages which are now enjoyed by half the villages of Lancashire, Yorkshire, and Durham.

WE confess that we do not quite know what to make of the "House-to-House" Company. At starting, recognising the success which had been attained in the installations already at work, they carried our entire goodwill, and although we should have preferred to see their advertising operations conducted on somewhat quieter lines, we still had hopes that they would speedily settle down to a steady and successful career, even though they did not immediately undertake to light the 27 provincial towns and 35 districts of the metropolis for which the advertisements assured us that "applications had been received." When, quite recently, the Board was strengthened by the accession of one of the most practical and capable engineers of our acquaintance, our anticipations of the speedy adoption of a sound and sensible policy were greatly strengthened. But on the morrow of this event a prospectus is issued containing announcements which we cannot profess to approve of. We are at loss to understand —seeing that the company was to hold no patents—on what grounds the sum of £5,000 (besides 100 founders' shares) is paid to Mr. ROBERT HAMMOND. If it is in consideration of his "gratuitous" services as managing director for two years—which, however, the wording of the prospectus seems to disavow—we are disposed to think that the shareholders would do better in the end to appoint some less important personage to that office. However, as the company is now afloat we shall continue to hope that its technical advantages will carry it through, in spite of the difficulties with which, as it seems to us, it has become somewhat gratuitously handicapped.

PROBLEM: It is required to determine whether an incandescent lamp (found burning) is run from an alternating or a continuous current, no electrical test to be made, and the circuit not to be interfered with. Solution (by Prof. S. P. THOMPSON, before the Physical Society): Take a hand-mirror and "waggle" it in front of the lamp; with an alternating current the filament as seen in the mirror will, as a general rule, undergo a periodical change of brightness which corresponds *not* to the current period, but to the revolutions of the armature. The fact that glow lamps fed with alternating currents sometimes flicker visibly to the naked eye has long been known. The explanation was first given by Prof. THOMPSON, in a lecture delivered at Finsbury College, a few weeks ago (see *Electrician*, Dec. 2, 1887, page 83). The effect is due to an inequality in one (or more) of the pole-pieces *combined* with a dissymmetry in the armature windings. A little consideration will show that neither of these causes is efficient in itself, but that their combination necessarily leads to the result described. Moral: In building alternating-current machines, special care should be taken to make the machine symmetrical in every part.

THE inhabitants of Roker, somewhere in the north of England, are said to be very indignant at the action of the district postmaster in causing to be closed a telephone call station which had established itself in the local post office. We are sorry for the inhabitants; but not so surprised as they seem to be. The incident is an example of what the POSTMASTER-GENERAL himself describes as the unsatisfactory state of affairs subsisting between his department and the telephone companies; but, except in its tendency to bring them to a crisis, it is hard to see how pushing telephonic enterprise into the very premises of the Post Office can help to mend matters. The local newspaper compares the action of the postmaster with that of the dog in the manger. The comparison would be fairer if horses were substituted for dogs: whereupon it will readily be seen that the Government hack is entitled to defend his stall and his hay against any intrusive steed that may desire to share his quarters. Surely there is room enough for the telephone companies' operations without needlessly provoking such contests as these.

MR. SWIRE SMITH is a great authority on technical education; but his paper, the other evening at the Society of Arts, was, it seemed to us, marred by the advocacy of some rather questionable projects as well as by some conspicuous errors in argument. Commencing with the admission that no systematic technical schooling has existed in this country until recently, he proceeds with his recommendations as if the industrial supremacy of England had long since departed; whereas it would be nearer the truth to say that her decline dates from the time when we abandoned the old methods of industrial training in favour of those new ones which are to be promoted by Technical Education Bills. Again, it is admitted that foreign artisans have hardly any leisure at all, and are very poorly paid compared with our own workpeople; yet it is argued that foreign rivalry is due to the time devoted to technical education, and that we ought to give it to Englishmen free of cost. On both these points we are profoundly sceptical. Our belief is that in a general way the genius can always take care of himself, and that if the ordinary run of artisans will not spend a little of their earnings and leisure to obtain it, technical instruction will be thrown away upon them.

IT is rather hard to discover any measurable public convenience that will be served by the establishment of telegraphic money orders. Some very elaborate precautions, out of proportion to the benefit conferred, will have to be taken to prevent the abuse or fraudulent use of the system; and we rather suspect it will give a new impulse to ready-money betting at race meetings. This may not greatly accentuate the evil, but it is not worth while to go out of our way to add a new attraction to the profession of racing tipsters, whose telegraphic remittances "till the very moment of starting" will be as good as hard cash in the ring.

OUR contemporary, *La Lumière Electrique*, contains an interesting paper by M. GASTON PLANTÉ upon the electrical phenomena which have been observed to precede or accompany shocks of earthquake. M. PLANTÉ cites a number of very interesting observations, but he has overlooked the highly remarkable instance chronicled in *The Electrician* of June 3rd, 1887, in which a telegraph clerk at Nice, who had his hand upon the instrument at the moment of the disastrous earthquake which devastated the Riviera, felt a most severe *electric* shock. M. PLANTÉ holds the opinion, in which most physicists concur, that earthquakes are, or may be, due to a variety of causes, amongst which electricity, as a rule, plays only a secondary part; he thinks, however, that in some cases, electrical disturbances may be a primary cause, though he does not venture to suggest in what way such an action may take place.

EXCEPT to remind us of the vicissitudes which the electric lighting industry had to encounter at the beginning of its career, the action brought by the Faure Electric Accumulator Company against M. PHILIPPART—judgment upon which was delivered last Monday in favour of the plaintiff company—has very little interest for us now. But no one can read Mr. Justice HAWKINS'S summing up and judgment without coming to the conclusion that the company's affairs were curiously managed, and by curious people—one of whom, for example, sought to repudiate a Board meeting resolution which he himself was mainly instrumental in passing.

A CORRESPONDENT writing to a provincial contemporary utters the following well-meant protest against the use of the grandiloquent term "installation":—

"Sir: It is curious to note how, whenever an account is given of the adoption of the electric light in any town or building, it is said that it has been 'installed' or that an 'installation' has taken place. Hitherto this term has been confined to the assumption of their duties and privileges by such high dignitaries as bishops, deans, or Knights of the Garter. Or, again, Cabinet Ministers or other great functionaries are said to be installed in office—the term having been etymologically derived from the fact of a special seat or stall being occupied by the office holder. But when this term is applied to the fixing in its place of a mere physical apparatus, is it not an abuse of language? Why should we not as well talk of a great installation of water having taken place when some new waterworks have been completed in a town? Indeed, if this sort of thing goes on we may expect to find it announced, in the case of a gentleman refurnishing his house, that 'the installation of the curtains was entrusted to Messrs. Smith and Co., whilst that of the bells was ably carried out by Messrs. Jones.'"

For our own part we should infinitely prefer the Anglo Saxon equivalent, "job." Mr. W. H. MASSEY, Electrician-in-Chief to Her Majesty the Queen, recently assured us that he never uses any other expression.

Vienna.—The western railway station is to be lit by MM. Ganz and Tarsa.

The Phœnix Fire Office Rules.—The twelfth edition of these rules was issued this week. No important change has taken place since the last issue.

The West Indian Cables.—The cable between St. Vincent and Barbadoes is now repaired.

United States Government and Submarine Cables.—A telegram from Washington states that the House of Representatives has passed the Submarine Cables Protection Bill.

Lighting of Lord Salisbury's House.—During the recess Lord Salisbury has had electric lighting introduced into the saloon and in the dining room of his house in Arlington-street.

Versailles.—A project is on foot for lighting the streets of Versailles by electricity, the idea being to transmit current from Marly. It is understood that Oerlikon dynamos will be employed.

Grenade-sur-Garonne.—This is a small place of 4,000 inhabitants, but a central station providing light for 500 lamps has just been opened here. The contractors were MM. Bonnet and Jongla.

The Electric Light on the Madras Railway.—It has been decided to employ electricity for lighting some of the carriages on the Madras Railway shortly, and for this purpose a provision of 15,000 rupees has been made in the Budget for the coming official year.

The Italian Telegraphs.—The Wheatstone automatic apparatus has recently replaced the Hughes instrument upon the line between Rome and Palermo, and also between Naples and Palermo. The line between Paris and Rome is now worked by the Baudot system.

Bournemouth.—On Wednesday evening Mr. Lynd delivered a lecture at Bournemouth on the electric light, with special reference to the storage system. The lecture was illustrated by a number of experiments, in which great interest was taken by a large and appreciative audience. A temporary installation was fitted up for the occasion by the Electrical Power Storage Company, of London.

Errata.—In Mr. Tomlinson's article on "The Thermo-Magnetic Properties of Iron and Nickel," p. 384, the following errata occur:—Heading of the fourth column of the table, instead of divided by $\frac{\Delta M_p}{\Delta t}$, read divided by 20, $\frac{\Delta M_p}{\Delta t}$. Heading of the fifth column, instead of $+M_p$ read $\times M_p$. In the 19th line of the second column of the page, 560°C. should be 650°C.

Fire Alarms at Portsmouth.—In our last issue a note appeared which was headed "Fire Alarms at Bristol," and was derived from a cutting taken from a Bristol paper, and sent to us by a Bristol correspondent. We now learn, however, that the statement referred to the erection of some fire alarm posts by the West of England and South Wales Telephone Company at Portsmouth, not Bristol, though there was nothing in the original to show this.

Electrical Engineering Football Club.—Notwithstanding the inclemency of the weather, there was a large assembly at the Prince's Hall, Piccadilly, on Friday evening last, the 24th ult., where a most successful dance, under the auspices of this club, took place. A programme of twenty dances (seventeen of which were waltzes) was got through just at the "wee sma' hour ayont the twal," general satisfaction with the band, stewards, &c., being freely expressed.

The Seel Lamp.—The "Seel" incandescent lamp has recently been attracting a good deal of attention in Germany. Like the "Khotinsky" the method of manufacture is kept

Digitized by Google

secret, for reasons easily guessed at. The lamp is made in all candle-powers up to 300, and the large lamps are classed as taking only 2 watts per candle-power. Our readers will not need to be reminded that "watts per candle-power" is the equivalent of bread per loaf when the weight is unknown.

The Electric Lighting Act, 1882.—In the House of Commons, in reply to Mr. Barclay, Sir M. Hicks-Beach said:—Since the passing of the Electric Lighting Act 59 provisional orders and five licenses have been granted to companies, and fifteen provisional orders and two licenses to local authorities. The Board of Trade are not aware of any cases in which the powers obtained are now being exercised. It is not possible to express an opinion as to the reasons which may have led to this result within the limits of a reply to a question. A Bill to amend the Act has been introduced in another place, on which the views of the Government will be stated and issues fully discussed.

Lighting of ss. "Ocean."—The trial trip of ss. "Ocean" took place on Friday last. The vessel was built by Messrs. Russell and Co., Greenock, for carrying petroleum in bulk, and is lighted throughout with electric light; there are fifty 20-c.p. Swan lamps distributed over the ship, including signal lamps, masthead, and anchor lamps. A 50-light Clyde dynamo is employed, which was manufactured and supplied by J. H. Carruthers and Co. The whole installation has been fitted up under the personal superintendence of Mr. James Campbell. On the installation being examined and tested, it was found to the entire satisfaction of the owner, and Mr. Flannery, of London, his consulting engineer.

The Foucault Pendulum Experiment.—A simple method of rendering visible the deviation of the Foucault pendulum has recently been devised by Mr. Campbell. The bob of the pendulum is replaced by a permanent magnet of a cylindrical form placed with its axis coinciding in direction with the suspending wire. On a point vertically beneath the centre of suspension is swung horizontally a light bar of some magnetic material, carrying a mirror, from which is reflected a beam of light. On putting the pendulum in vibration in the vertical plane which contains the bar, the latter follows the deviation of the pendulum, which is thus rendered very visible by the corresponding reflection of the luminous beam.

Exeter.—At the conclusion of a lecture on electric lighting delivered last week by Mr. Wharton at the Victoria Hall, Exeter, and which was presided over by the mayor, the following resolutions were unanimously adopted:—"That in view of the great satisfaction given in the lighting of Exeter streets by electricity, this meeting is of opinion that it would be to the interest of the city, and add to its attractiveness and prosperity, if the public streets were permanently lighted by the system of arc lighting now in use." "That it is the desire of this meeting that a local company should be at once formed for the purpose of supplying Exeter with the Thomson-Houston system of electric lighting for public and private use."

Earth Currents during the Recent Solar Eclipse.—A diurnal period of variation in the intensity of earth currents has long been recognised, but it has not yet been settled whether the action is due to direct electro-magnetic induction from the sun, or whether it is an indirect result of the change of temperature. We learn from the Moscow *Technik* that in order, if possible, to throw some light upon this question, careful observations of the earth current upon the Vladivostok-Nagasaki cable were made during the recent eclipse of the sun. It appears that up to the commencement of the eclipse the current was of the normal value, but it then commenced to *increase* until during the period of totality it had become twice as large, after which a decrease set in, and at the end of the eclipse it had again attained the normal value.

The Electric Lighting of the Leeds Fine Art Gallery.—The Electric Lighting Committee of the Leeds Corporation met yesterday to consider what form of power should be employed for driving the dynamos in connection with the electric lighting of the Leeds Fine Art Gallery. After discussing the respective claims of steam, gas, and compressed air as motive powers, it was decided to adopt the latter, as being generally more suitable for this particular purpose; as getting rid of risk from fire; as obviating the use of fires, boilers, and long chimneys, and as being of service in connection with ventilation. It was therefore decided to accept the offer of the Compressed Air Company to supply compressed air, and also to furnish five 25 horse-power engines and a meter, at a rental of £50 per year for three years. The Town Clerk was instructed to prepare an agreement embodying this arrangement, and a meeting of the committee will be held early next week, when the terms will be duly subscribed to.

Tests of Electrical Welding.—Prof. A. E. Dolbear writes to the American *Engineering Record* as follows:—"I have had made nearly a hundred tests of the tensile strength of electrically-welded bars of iron, steel, and other metals. The results were of such a character that I can state positively that with Thomson's welding process it is possible to weld both wrought iron and steel so that the weld is as strong as the same cross-section in another part of the bar; that the appearance of the fracture is fibrous for iron and generally granular for steel, the strength of this granular steel being on some samples as high as 125,000 pounds per square inch; that the process is such that the welding is homogeneous from necessity. I had a number of bars welded by an expert blacksmith, and a number of similar ones by the electrical process for comparison, with the result that the electrically-welded bars were much stronger than those welded by the ordinary process. The bars were of various sizes, up to an inch and a half for iron, and three-fourths of an inch octagon steel."

Glasgow City Bazaar.—The lighting of the Glasgow Bazaar and City Hall with the Thomson-Houston system (arc lamps) was completed and formally inspected by the members of the Town Council on the 14th inst. Everything was satisfactory. The engine, which is a 16 horse-power compound, was made by Robey and Co., Globe Works, Lincoln, for Mr. Miller, the agent to the Thomson-Houston Co, at Glasgow, and was running under brake from 9 a.m. till 4:45 p.m., when it was stopped to put the machine belts on, and at 5 o'clock was started again for the official test of six hours, with the full load of 34 lamps. At 11 o'clock all bearings were quite cold. One half the lamps (*i.e.*, those in the bazaar) were thrown off, and the remainder were kept going till 3 a.m. The engine, therefore, had a continuous run (except the 15 minutes for putting on belts) from 9 a.m. one day until 3 a.m. the next. The oiling arrangements are most satisfactory, and there would appear to be nothing to prevent continuous runs for an indefinite time. The governor acted perfectly when the half load was thrown off, and there was no perceptible change in the engine speed.

The Electric Light at Civil Service Stores.—Speaking at the annual meeting last Monday of the Civil Service Co-operative Society (the Haymarket Stores) the chairman,

Digitized by Google

Mr. Charles J. Cox, stated that the electric light had been partially introduced into the stores. They had found it of very great advantage. Many of the articles they sold were liable to injury from the fumes of gas, and those articles were now protected by the use of the electric light. If it should prove thoroughly satisfactory they proposed to extend the use of the electric light throughout their buildings.—Mr. Bannister, the chairman of the Civil Service Supply Association (of Queen Victoria-street, City, and of Bedford-street, Strand), stated at the annual meeting of the association on Tuesday that the increase of about £1,500 in the fixtures was attributable to their having adopted the electric light at Queen Victoria-street. The light was now used on almost every floor, and they had been compelled to put it in the basement. They were now working such a large number of men there that it was necessary, for the purposes of health and safety, to use the electric light wherever they could instead of gas.

Electric Traction in Austria.—The Vienna correspondent of *Industries* says that Herr Fischer, a civil engineer of that town, has obtained a concession for an electric railway between Vöslau and Rauhenstein, near Baden, and from there to Leopoldsdorf. The length of the line being considerable, Herr Fischer will probably use storage cars; Julien accumulators are now being tested in the Electrotechnical Institute, and a trial of these cells for tramway work in competition with Reckenzaun cells will shortly take place. A central station for the supply of electricity has recently been erected at Neuhaus, in Bohemia. The contractor is Count Czernin, a landowner in that district, and he has arranged for the supply of light to the Commune for 20 years. Power is obtained from a turbine, and there are at present two dynamo machines installed. The distribution is on the three-wire system with feeders. All the leads are carried on poles overhead. The streets are lighted by 85 16 candle-power glow lamps, and in private houses there are at present 365 lamps fixed, but the demand is constantly increasing. To provide against breakdown a battery of 1,000 storage cells is now being laid down.

Accident to Overhead Electric Light Wires in New York.—According to a New York paper an overhead electric light wire in that city recently became red hot. The account proceeds as follows:—"The wires belonged to the plant of the United States Electric Light Company, and ran on poles on both sides of Sixth Avenue. At 8 o'clock the numerous street lights which the wires operate were brightly burning. Suddenly a spark of fire appeared on the branch wire which operates the arc light in front of some grocery store. In an instant the glow had spread to the main wire, which for a distance of 100ft. or more emitted a dazzling brilliancy. The illumination speedily attracted an immense crowd. This crowd continually increased in size, and the matter was promptly reported to the police station. In the meantime the avenue was blocked, and the police had great difficulty in keeping the crowd at a safe distance from the glowing wires overhead. To increase the excitement, the wire on the opposite side of the street also burst into flame. One excitable man ran to the engine house in Tenth-street, and called for assistance. Several firemen responded; but, of course, could do nothing. A cross-bar on one side of the poles caught fire from a tongue of flame; but beyond the injury to the wires and pole the loss resulting from the accident will be slight. Linesmen of the electric light company, who handled the blackened wires as soon as they were cold, decided that the snow and ice had in some way formed a connection between the oppositely-charged wires and completed the circuit."

The Indian Telegraph Department.—The following particulars relating to the progress of Indian telegraphs are given in the Administration Report for 1886-7:—The Indian telegraph system embraces every military station and every town of importance throughout the length and breadth of the vast Indian Peninsula, including the territories under Native Chiefs and Princes, as also military stations and towns in Lower Burma and most of the military posts recently established in Upper Burma, and on the 31st March, 1887, there was a total post mileage of 30,034 miles, with a total length of 86,890 miles of wire, in addition to 196 miles of cable connecting India with Burma. During the year under review the post mileage was extended by 2,524 miles, and the length of wire by 5,410 miles. The number of telegraph stations open to the public on 31st March, 1887, was 2,389, of which about 50 per cent. have been opened since April, 1883. There are two classes of messages, State and private, and we give below a statement of the number of each class during the year, with their value:—

	Number.	Value Rs.
State Inland	452,277	16,20,626
Private Inland	1,683,753	18,17,798
State Foreign	6,898	78,494
Private Foreign	373,893	13,13,321
Total	2,516,826	48,30,239

These totals represent an increase in the number of messages sent, as compared with the preceding year, of 226,888, and of Rs. 8,69,187 in the value of the messages sent.

Remarkable Discharge of Atmospheric Electricity.—A correspondent writes as follows:—"A most violent discharge of electricity was observed on board the Danish steamer 'Constantin,' coming from Newcastle and bound for Copenhagen, on Friday morning, February 10th, when about 160 miles distant from the English coast. Although the thermometer was at freezing point thunder and lightning began some way off, between 4 and 5 o'clock a.m. At about 6 o'clock a tremendous report was heard, sounding like thunder, and the captain describes the appearance of the vessel as if it were shrouded in a mass of bright red flames, which lit up the surrounding waves. The phenomena was all the more surprising as the thunder and lightning appeared to be at some considerable distance from the steamer, and it could not be compared to an ordinary thunder-clap and lightning flash, being far too violent and no regular flash of lightning being seen. The shock was so great that several men in various parts of the ship were knocked down, and the first engineer was under the impression that a boiler explosion had taken place. The whole thing only lasted a moment, but it was attended by a violent wind, and St. Elmo's lights were seen on the tops of the masts and elsewhere. On arriving at Copenhagen the captain found his suspicions confirmed of alterations having taken place in the deviation of the ship's compasses. The alterations were greatest on S.S.E. and N.N.W. courses, where the deviation, from having been 7 degrees westerly, had become 5 degrees easterly. The vessel was, when the electrical discharge took place, steering E. to N."

Communication with Lighthouses and Lightships.—Referring to the resolution passed by the Associated Chambers of Commerce in favour of telegraphic communication with lightships, *The Times* says:—"The motion introduced by Mr. Bayley, of Plymouth, for the connection of coastguard stations and lighthouses and lightships with the general telegraphic system of the country, and thus with each other, was well deserving the favourable reception which it met. Mr. Bayley's case is a very strong one, and the need to which he refers is so

Digitized by Google

great and so obvious that it will be a surprise to our readers to learn what imperfect provision has been made for it. There are at present only a few signalling stations, belonging not to the public, but to Lloyd's; and, apart from these, the gun and rocket are the only available signals of distress. These signals may not be heard, or may not be rightly understood. Precise they can very seldom be. The lighthouse or lightship may see distinctly what has happened, or what want is seeking to be relieved, but it has no adequate means of passing on the information. There have been plenty of instances serving to demonstrate the pressing importance of not suffering things to remain as they are. The steamer 'Nordstern' ran on shore under the Start lighthouse, and was there seen at midnight. From want of communication between the Start lighthouse and the points at which help was to be had, it was four and a half hours before any help came, and 10 hours before a lifeboat, only five miles away, arrived Again, when the steamer 'Soudan' was wrecked, close to the coastguard station at Hope Cove and 15 miles from Plymouth, it was seven hours before the news reached Plymouth, and 12 hours before a tug came to her help. Such cases as these are decisive, but they do not make up the whole of what may be said. As regards coast defence, the matter is of an importance which it would be hardly possible to exaggerate. The want to which Mr. Bayley refers was felt practically in the course of the late jubilee manœuvres, and in the event of war it would no less certainly recur with disastrous results at a time no longer of play, but grim earnest. Mr. Bayley has done his part. He has brought the subject prominently under notice. It remains for the responsible authorities to deal with it as the case demands."

Electrolytically-Formed Copper Pipes.—According to *Engineering*, Mr. W. Elmore, of Cockermouth, has at last succeeded in obtaining electrolytically a deposit of fibrous copper. By this method, says our contemporary, such an article as a steam pipe can be produced without weld or joint, and having a tensile strength from 50 to 100 per cent. in excess of first-class brazed pipes. Further, this result can be attained with the use of a very inferior quality of copper, and at a cost which will enable the electrolytically made article to compete in the market with the customary varieties. Of course there is nothing new in depositing copper in a tubular form; but hitherto such metal has been too brittle to render it reliable for use in circumstances under which it is exposed to great stress. For copying engraved plates and for the rollers of calico-printing machines deposited copper has been used with great success, and when it has been thrown down very slowly it has been possible to produce very satisfactory qualities of metal for these purposes. The novelty introduced by Mr. Elmore, however, lies in breaking down the crystals almost immediately they are formed, and pressing them out into a fibrous form in which they are interlaced and matted together. To this end the iron core or mandrel on which the metal is deposited is kept constantly rotating in the bath, and an agate burnisher is slowly moved backwards and forwards lengthwise of the cylinder, as if to cut a screw thread upon it. The speeds are so arranged that a layer of copper seven-thousandths of an inch thick is deposited between each reciprocation of the burnisher. When the required thickness has been attained the mandrel is lifted out of the bath and placed in a vessel supplied with superheated steam. In a few moments the expansion of the copper detaches it from the iron, and the shell can be stripped off. Pieces cut from such tubes have been submitted to breaking tests by Messrs. Kirkaldy and Co., Prof. Kennedy and Prof. Unwin, and have broken at strains varying from 27 tons to 41 tons per square inch, with an extension varying from 5 per cent. to 7½ per cent. in a length of 10in. The metal can be worked under the hammer most easily, and can be drawn, bent or compressed without annealing and without any tendency to crack. Specimens polished and submitted to the microscope show that the electrolytic metal has a perfectly compact and homogeneous structure, while drawn copper is a honeycombed mass of crystals, only connected together at points. The success which has attended the experimental stage of Mr. Elmore's process encourages the belief that absolute security from burst copper steam pipes can be secured in the future, and that we are on the eve of being supplied with a greatly improved quality of copper for all purposes.

Electric Railway Signals.—A system of electric signalling, by means of which a signal is with facility and certainty given to the driver of an engine by indicator in front of him, has been before the railway world for some time; but although it would effectively prevent accidents in fogs, and reduce the heavy cost at such times for signals and fog signalmen, it has not been taken up by our railway companies. This is partly due, says the *Engineer*, to the fact that as each engine must be fitted with a small apparatus, it would be necessary for the complete safety against accident that every engine running on a line, to whatever company it may belong, should be so fitted, and hence for some lines the several companies would have to agree to its simultaneous adoption. The invention is the subject of patents held by the Electric Signal Company, and it has been tested with success on the Belfast Central Railway and on the Penally and Tenby line. The following is from a report of Dr. J. Hopkinson, F.R.S., on the system, which is Enright's patent:—"On August 22nd I visited Tenby and examined the apparatus put up by Mr. Enright at Penally Station, and on the line between Penally and Tenby, and I fully tested it in operation. The apparatus has primarily two purposes to fulfil, first, to enable the signalman to communicate with the driver of a train in motion electrically without the use of detonating signals or distant visual signals; second, to record the passage of all trains along the line automatically. I carefully verified the working of every part of the apparatus, both from the point of view of the signalman at the station and from the point of view of the driver on the locomotive. In my presence every part of the apparatus performed perfectly; the signals on the locomotive were unmistakable, and the contacts were properly recorded upon the drum at all speeds of the locomotive up to fifty miles per hour, the maximum it was practicable to obtain. In the experiments I witnessed at Tenby Mr. Enright's apparatus worked most satisfactorily, and it was evident that he had employed much skill and thought in working out the details of his invention, particularly in securing regularity in the electrical contact between the locomotive and the road. The *à priori* arguments in favour of electrical signals, instead of, or in conjunction with, the ordinary semaphores, are strong, but the advantage in their use would appear to be exceedingly great as superseding the barbarous system of detonators now used in fogs, and for this purpose they might be used in conjunction with the ordinary visual signals, and so be subject to the existing interlocking apparatus on which safety so much depends. The expense of introducing Mr. Enright's system in this way could not be very great." The fact that the system is not in use yet would appear to be due to its being insufficiently represented before the railway companies; but as the patents are, we understand about to be sold, this defect will perhaps be removed.

THE RISE AND PROGRESS OF TELEPHONY IN THE UNITED KINGDOM.

(Continued from page 338.)

In our last chapter we stated that early in 1885 the United Telephone Company completed an arrangement with the Post Office for the transmission of telegrams to and from the central telegraph office and the houses of the company's subscribers. It will be of interest to trace briefly the steps by which this and other important concessions to the telephone companies were obtained from the Post Office.

We have already given an account of the suit brought against the United Telephone Company by the Post Office, on the ground that a telephonic message was a telegram within the meaning of the Telegraph Act of 1868, the result of which was a judgment against the company. The United Telephone Company very wisely decided to accept the decision of the Court of First Instance, instead of carrying the case to the Court of Appeal, on the understanding that they would be allowed to carry on their work as licensees of the Postmaster-General. The original license granted to the United Telephone Company, as also those subsequently granted to other companies, ran from the 1st of January, 1881, for a term of 31 years, the Postmaster-General, however, reserving to himself the power to purchase, at a price to be settled by arbitration, in 1890, 1897, or 1904. Each license was granted for a particular district only, generally included within a radius of five miles, and a royalty of 10 per cent. was payable by the company to the Post Office on the gross earnings of all their exchange wires, and also of any private wires rented from them, with the exception of wires connecting two establishments occupied by the same person or firm. The permission to extend the radius was frequently refused, and when granted the Post Office usually demanded a royalty of 12½ per cent. on all wires running outside the original radius. The companies were not allowed to establish trunk lines between different towns, except upon conditions which were practically prohibitive.

Subscribers to the Post Office telephones were allowed to have telegrams transmitted to and from the post offices; but this privilege was only granted to the subscribers to the telephone companies' exchanges on the payment of five guineas per annum by each firm desiring the privilege, in addition to the ordinary tariff for the telegrams transmitted. These restrictions, as was to be expected, greatly hindered the development of the telephone system, and in the spring of 1884 a memorial was presented to the Postmaster-General, Mr. Fawcett, by the Edinburgh Chamber of Commerce asking Her Majesty's Government to grant such facilities as would encourage and develop the telephone system, without unduly interfering with the revenue of the Post Office. This was followed up by questions on the subject in the House of Commons, and ultimately Mr. Fawcett, who showed every disposition to consider the requirements of the telephone companies in a reasonable spirit, decided to request them to endeavour to come to an agreement as to the modifications of their existing relations with the Post Office which in their opinion would meet the public requirements, and to communicate the result to him in writing, as he considered that it would be desirable to give greater freedom to private enterprise by relaxing some of the conditions contained in the licenses hitherto granted.

In reply to this request the United Telephone Company, and its affiliated companies, submitted three distinct proposals, and the four non-affiliated companies likewise submitted statements of their views, which, in the main, were to the same effect, except that the latter asked for protection from competition in the towns where their exchanges were established, a proposal which Mr. Fawcett declined to entertain.

The three alternative suggestions submitted by the United Telephone Company were as follows:—

1. That each company should be allowed to carry on business within the district for which they held a license in any way they might think fit, and that in lieu of the royalty of 10 per cent. then paid to the Post Office on their gross receipts, the companies should undertake to make good to the department any loss which the local revenue might suffer from the development of telephonic communication within the district, allowance being made for the normal growth of the telegraph revenue based on the receipts of the three preceding years.

2. That the existing royalties should be reduced from 10 per cent. to 5 per cent.; that the same guarantee as that contained in the first proposal should be entered into; that the existing radius for exchange licenses, then generally fixed at from four to five miles, should be extended to fifteen miles; and that various other restrictions should be removed, giving practically the same freedom as that embodied in the first proposal.

3. That the existing royalty should continue to be paid as before, but that the other modifications suggested in proposal 2 should be made.

After careful consideration, Mr. Fawcett decided that the first two proposals must be rejected, as in the first place the acceptance of a guarantee would involve granting the local monopoly to the company then in possession, and he considered that if there were to be a monopoly it ought to be in the hands of the Government, and in the second place the Post Office would be hampered in introducing any change in their then existing telegraph tariff.

There remained the third proposal, and this, the Postmaster-General considered, offered a basis for a settlement, and the terms which he proposed and stated in the House of Commons in August, 1884, were as follows:—

1. That the Government should reserve the right either to carry on telephone business itself or to give licenses to any responsible persons to carry on such business in any part of of the country, whether any previous license had been granted for such part of the country or not.

2. That the condition that the companies should furnish the Post Office with an unlimited supply of any patented instruments used by them should be abandoned.

(We may note that great stress had been laid on this abandonment in the proposals of all the companies.)

3. That as the extension of the radius to fifteen miles asked for by the companies would involve in principle just the same objections as fixing the radius, as at present, at four or five miles, no limitation of radius should be maintained.

4. That with the abolition of any limit of radius and consequent extension of areas, the distinction between the conditions on which the companies had hitherto been allowed to use trunk and exchange wires should not be maintained, the companies being in future able to provide themselves with trunk and exchange wires alike.

5. That call offices should be allowed for the transmission of oral messages.

6. That, having regard to these concessions, and to the desirability, as far as possible, of securing simplicity of accounts between the Post Office and the companies, *the royalty of 10 per cent. then paid on gross receipts should be extended to their receipts from the private wires hitherto exempted.*

7. That the Post Office should incur no obligation to provide way-leave or to erect wires for the companies.

8. That in order to maintain the distinction between written telegraphic messages and the spoken communications made by means of the telephone, *the telephone companies should not accept or deliver any written message at any point.*

This offer on the part of the Post Office conceded in several points more than had been asked for either by the companies or the public, and was received as being, on the whole, a broad and liberal concession to an enterprise the encouragement of which was imperatively demanded by the public interest.

Strong opposition was, however, offered by the companies to the sixth clause. Colonel Raynsford Jackson, Chairman of the National Telephone Company, pointed out that the demand of a royalty on private wires would have the effect of placing the companies at a disadvantage in competition with private firms, as private telephone wires communicating only between premises occupied by the same person or firm, did not require the sanction of the Postmaster-General, and might therefore be erected by private firms without payment of the royalty.

Digitized by Google

With respect to the eighth clause Colonel Jackson suggested that the wants of the public could be met without in any way infringing this condition, if the Postmaster-General would allow the various exchanges erected by private enterprise to be connected with the Postal Telegraph Office, and permit the subscribers to send, through wires which could be switched into operation when required, messages to the Postal Telegraph Office to be transmitted as telegrams, so that there would be no delivery of written messages by the companies, but there would be a great increase of business to the Postmaster-General through the instrumentality of the various companies' exchanges. In addition to giving subscribers the privilege of sending Post Office messages through the Postal Telegraph Office he suggested that the Postmaster-General should also, when he received such messages for the Telephone Exchange subscribers, deliver these messages to them through the exchange, the Post Office to charge their ordinary rate for the telegrams, and to abandon the annual rent charge of five guineas previously demanded from firms availing themselves of this privilege.

Mr. Fawcett finally decided to grant the facilities asked for, and also to abandon the claim for royalties on private wires hitherto exempt from them. His death occurred in November, while the negotiations with the companies were still in progress, but they were carried on on the same lines by his successor, Mr. Shaw-Lefevre, and, with the above mentioned modifications, Mr. Fawcett's proposals were definitely adopted.

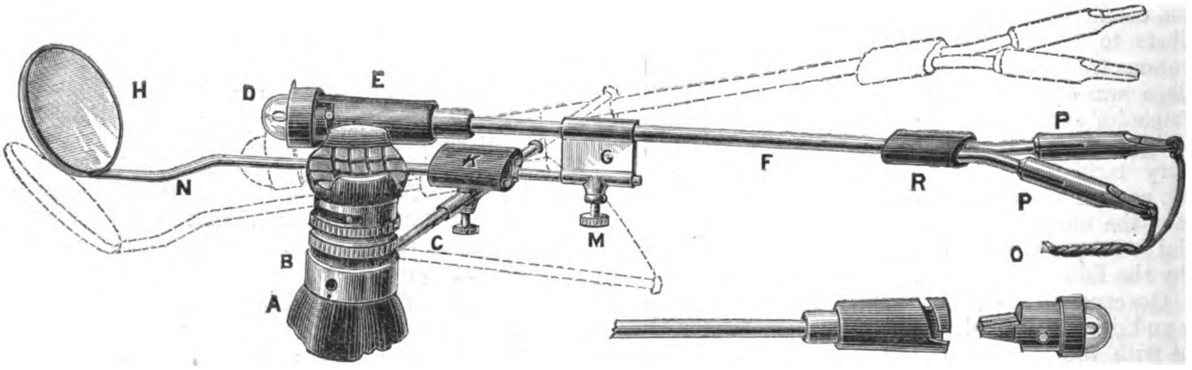
VESEY'S ELECTRICAL ODONTOSCOPE.

We illustrate herewith an electrical appliance, designed by Mr. Vesey, for the use of dentists in stopping teeth. Mr. Vesey's electrical laryngoscope, which was described and illustrated in *The Electrician*, 21st January, 1887, page 244, is now in use all the London hospitals, and by many of the leading surgeons, not only in this country but also on the Continent. The illustration (Fig. 1) together with the lettered description will make the details perfectly clear. Fig. 2 shows the incandescent lamp slipped out of the socket, in which it is held by a bayonet joint; it will be seen that the method of attachment is extremely simple. The filament is joined to two small platinum wires which lie flat against the wooden holder, and when fitted in to the socket are pressed against the insulated platinum jaws.

The battery used is a 4-cell Victoria Leclanché, made for Mr. Vesey by the General Electric Company, and is found to answer its purpose admirably. The lamps are made by the Edison Company, and the instrument is made by Messrs. Weiss and Son, of Oxford-street.



A Ordinary dentist's gag, fitted with the usual spring adjustment for various mouths.
B Revolving collar, with arm C attached.
D Incandescent lamp.
E Bayonet joint, to release lamp instantaneously.
F German silver tube sliding through spring clip G.
H Mirror, either plan or magnifying.
M Set screw to clamp G at any point on N.
N Sliding rod holding mirror.
O Flexible cord to battery.
PP Spring terminal to flexible cord.
R Ebonite to receive tube F, and terminals PP.
K Ebonite supporter for rod N, and sliding on rod C.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

CHAPTER VIII.—*The Calibration of Current Indicators.*

(*Continued from page 410.*)

82. It will be noticed that the instrument is very unsensitive above 70 degrees and below 10 degrees—that is, considerable change in the current strength is necessary to produce appreciable change in the deflection; but at angles between 20 and 50 degrees the instrument is most sensitive. The steeper the incline of the curve, the more marked will be a change of deflection for a change of current.

The value of any current may now be found by reference to the curve; thus, if 12 degrees deflection was observed the corresponding current could be found by placing the edge of a flat ruler at number 12 on the vertical degree ordinate, and the edge of the rule being horizontal would cut the curve in some point. Marking this point lightly with a pencil the rule would be turned vertically in a line from the point on the curve to the horizontal ordinate. This would cut the latter at 10 milliamperes, which is the required current. It should be mentioned here that practical working curves are usually about four or five times the size of the one in the figure; in fact, the larger the scale they are drawn to and the more observations taken from which to plot them the better.

83. This curve is seen to exhibit no "straight line law" or proportionality between currents and deflections except, perhaps, up to 10 degrees—that is, every scale degree movement of the needle does not represent an equal increase of current. As simple examples of proportionality between indications and scale degrees, there might be cited the Salter's balance, where every scale degree movement of the pointer means an equal increase of weight suspended to it; or the steam-pressure gauge, in which every equal scale division means equal increase in steam pressure; or the thermometer, whose scale divisions are equal, and mean equal rises in temperature; or the ordinary clock, whose dial is divided into twelve equal parts, each of which mean equal intervals of time. If we were to plot the relation between degrees deflection, and weights in the spring balance, or between divisions deflection, and pressure in the steam gauge, or between divisions rise of mercury, and temperature in the thermometer, or between movements of clock hand and intervals of time in the ordinary clock, precisely in the same manner as the readings are plotted for the detector in Fig. 48 *ante*, we should get a straight line instead of a curve, showing absolute proportionality between the indications and degrees of scale. This straight line law or absolute proportionality is very desirable in instruments used in the measurement of large currents used in electric lighting, and has been very successfully carried out by

Digitized by Google

Profs. Ayrton and Perry in their ammeters, or current measurers, in which the divisions through which the needle is deflected are made equal to each other and correspond to equal increments in the current strength throughout the whole of the scale. Messrs. Walmesly and Mather have devised a galvanometer whose deflections follow the proportional law up to about 50 degrees. These instruments will be referred to again in detail, when the different kinds of galvanometers are examined.

84. If now the indicator to be calibrated is of the horizontal type, we should expect to find the needle move round a large number of degrees for a very small current, since the horizontal mounting of the needle, whether by a pivot or by a silk fibre suspension, admits of greater sensibility. One or two cells would then furnish the maximum current required, the largest deflection being obtained with the battery connected direct to the instrument, and the deflection being gradually reduced by the addition of extra resistance to the circuit. We shall in this example also select cells (such as secondaries or large size primary cells) of low resistance, negligible in comparison to the resistance of the instrument coils

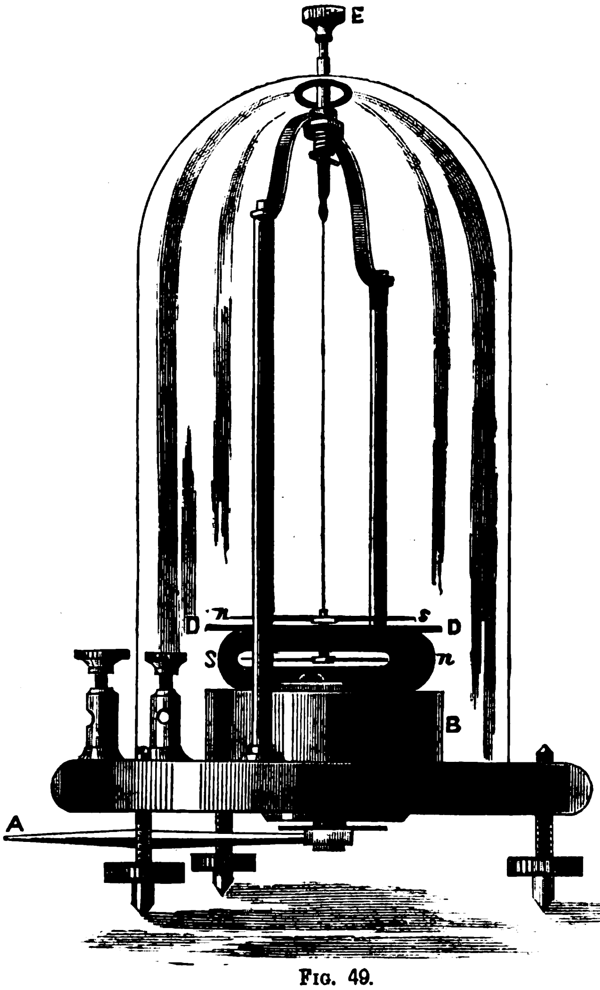


FIG. 49.

A curve taken in this way of the astatic instrument shown in Fig. 49 is here appended. The two needles marked *n s* in reverse ways may be seen in the figure, suspended by a silk fibre, one being inside and the other outside the coils forming the astatic system. To set the instrument it must be turned round till the needles are parallel to the plane of the coils, which will be the case when the top needle points to zero on the graduated dial D. This can very conveniently be effected without shifting the base of the instrument when once levelled by moving the coils alone, these being attached to a hollow wooden base, B, capable of being turned about the centre by means of the handle A through an angle of about 60 degrees. The base B contains a sufficient length of flexible wire, spirally wound, to admit of this movement of the coil while it is connected permanently to the two terminals. It is important to see that the lower needle does not touch the interior of the bobbin during any part of its movement, and once the needles are perfectly still, this can be tested very well by moving the handle A right and left through its full range, which should not cause the slightest movement of the needles. If it does, the interior of the bobbin should be looked through to see if the lower needle is too high or too low, and its height can then be adjusted as required by raising or lowering (not screwing round) the suspension head E, to which the silk fibre is attached.

85. The instrument, after being "set" as described, should be connected to a box of standard resistance coils A, and a low-resistance cell, as shown in Fig. 50. The higher the resistance of the coils in the instrument the more margin may be allowed for the resistance of the cell while considering the latter as a negligible quantity—that is, if the coils were, say, 1,000 ohms, as high a resistance as 3 or 4 ohms in the cell would be practicably negligible. Horizontal instruments are usually wound to resistances from 500 to 1,000 ohms. If there is no very low-resistance cell available, such as a primary battery with large plate surface in use for lighting, or a charged accumulator, or a large size Daniell or Fuller cell, three or four cells may be connected together in multiple arc—that is, all the zincs together to form one terminal of the battery, and all the coppers or carbons together to form the other. This will then act as one cell of as many times the amount of plate surface as there are cells connected up, and the internal resistance will be diminished in proportion to the number. Thus, four cells in multiple arc would have one-fourth the internal resistance of one cell, five cells one-fifth, and so on, while the E.M.F. of the combination,

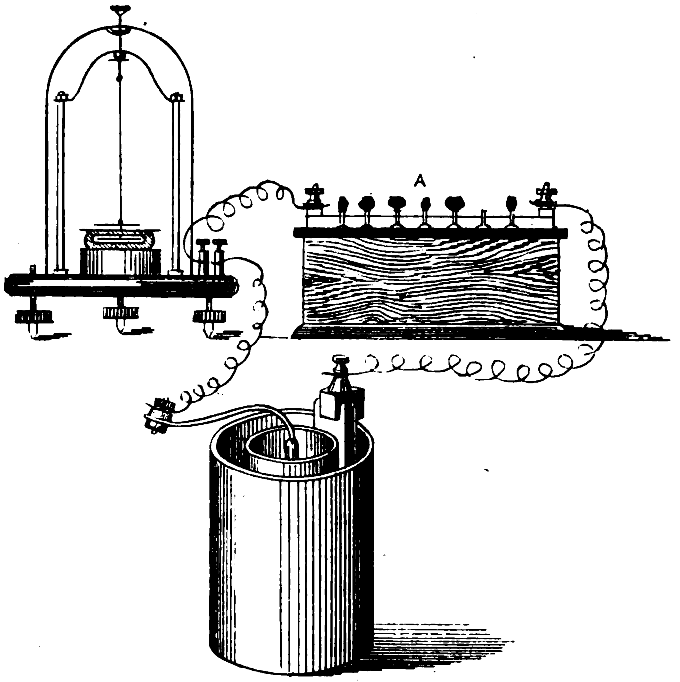

FIG. 50.

in this manner, of any number of similar cells would be the same as that of one.

(*To be continued.*)

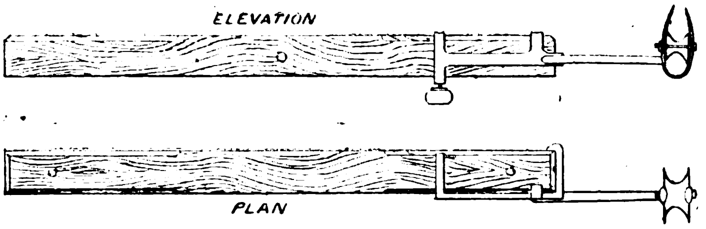
RENEWING TELEGRAPH AND TELEPHONE WIRES.

The frequent interruptions caused by earths and contacts during renewal operations have at all times been a source of much annoyance to telegraph engineers. Considerable attention seems, however, to have been given to the matter lately, and various appliances have been designed to avoid stoppages from this cause and to maintain uninterrupted communication while new wires are being run.

Digitized by Google

Particulars have been furnished us of another appliance designed and patented some time ago by the Caledonian Railway Company's engineer, Mr. Dunn, and excellent results are said to have been obtained by means of this tool. Its use, instead of retarding work, as might seem at first sight to be the case, is said to facilitate the operations to such an extent that at least 20 per cent. more can be done in the same time. The runner, as shown in the adjoining figures, is attached to the arm by transverse jaws and an under pinching screw, and the outer end carries a free pulley, over which the new wire is run. The pulley is a special feature of the tool, as it offers little or no resistance to the wire, and in drawing out enables one man to do the work hitherto done by two. The "scouring" and "skinning" which take place when wire is drawn over rough ground, or over arms against insulator bolts or other rigid surfaces, are also completely obviated, and the wire is got into position without the zinc coating being broken or in any way impaired.

The method of using is as follows:—One runner is attached to a long arm on each pole along the section over which a coil of new wire will run. The wire is then drawn out over the runners, and as those project it is kept clear of the standing wires on the poles. When drawn out, the wire is viced up on the runners and exchanged with the old wires, after which the latter is cut down. The whole process is gone through without the new or old wire getting foul of any other wire on the poles. It will be apparent that it is much easier to lift the bight of the wire on to the runners as it is being drawn out than to thread the wire over the arm between the insulator and the pole, as is done under the old system.



A number of appliances had been designed and tested by Mr. Dunn, but it was found after considerable experience that the one now described is most suitable for the work. The advantages claimed are that it is light and portable, and can be quickly and securely attached without boring or cutting the arm. It provides complete immunity from interruptions and facilitates the work. It prevents injury to the anti corrosive coating of the wire, and adapts itself to the system of drawing wires out.

OUR ELECTRICAL DEFENCES.

The report of the committee appointed to consider the defence of our naval and mercantile ports has just been issued, and, as was fully to be expected, the greatest possible stress is laid upon the importance of submarine mining operations—a phrase which, it is scarcely necessary to add, is synonymous with that of "electrical defences." The report states that—"It is satisfactory to note that very great progress has been made in carrying out the submarine mining defences. In many of our ports the work is well advanced, and the committee strongly urge that, in every port intended to be defended at all, to which it is applicable, this work should be pushed forward to completion as rapidly as possible; and they are of opinion that, as funds become available, efforts should be made to complete these defences at the most important ports instead of spending small sums upon many ports. The committee consider, moreover, that steps should be taken to afford additional opportunities for practice to all those (whether belonging to the Regular or the Auxiliary Forces) who will have to take part in submarine mining operations in time of war." In view of this statement it may confidently be anticipated that steps will be taken at an early date to increase the number of Volunteer Corps for harbour defence. We have already taken the opportunity of commending this scheme to the attention of our readers (see *The Electrician*, 28th October, 1887, p. 511).

Through the courtesy of Messrs. Armstrong and Mitchell, of Newcastle-on-Tyne, we have recently had the opportunity of inspecting and experimenting upon the electrical appliances of Capt. McEvoy, which form a portion of the war *matériel* manufactured by that firm, and next week we hope to give a full and illustrated description of the apparatus, which, we may add, has not before been published.

We append a table taken from the report already referred to, which will enable our readers to judge for themselves of the importance which the electrical defence of our harbours has already assumed.

THE ELECTRIC LIGHTING OF THE SAVOY THEATRE.

This installation, which was the first on a large scale in which incandescent electric lamps were employed, was completed in 1881, and was used for the first time to light the theatre at the evening performance on the 10th of October of that year. The installation was carried out by Messrs. Siemens Brothers, under whose charge it has remained up to the present time, and from the beginning the lighting has been thoroughly satisfactory in every respect. The stage is at present lighted by 715 white lamps or 601 blue ones, the latter being used for the night scene in "Pinafore," now being revived at the theatre, and their number is therefore intentionally less than that of the white ones. These lamps are nearly all on one simple shunt-wound dynamo, and their brilliancy is regulated by inserting resistance in the circuit of the field-magnets, an arrangement which has the advantage of avoiding almost entirely the waste of energy resulting from the ordinary method of inserting the resistance in the external circuit. The battens which carry the stage lamps, other than the footlights, are made entirely of incombustible materials. The insulated cables, proceeding from the stage ladders which carry the lamps to be placed on the movable scenery, terminate in triple plugs which are inserted into contact pieces on the stage, and the change from white to blue or *vice versâ* is made for these, together with the other stage lights, by means of a single switch.

The auditorium is lighted by 150 lamps arranged in groups of three, supported on three-fold brackets projecting from the different tiers, and each lamp is enclosed in a ground-glass or opal shade, so that the light is soft and pleasing. The corridors, refreshment rooms, and offices are lighted by 165 lamps, and 148 are in use in the dressing rooms behind the stage. The maximum number in use at one time is, therefore, 1,178, the total number fitted being 1,779. They are all of the Edison-Swan type. The lamps are all arranged in parallel on three main circuits, one of which is in parallel with a circuit containing two arc lamps, taking 40 amperes, placed outside the theatre. The current is produced by three Siemens dynamos of the S.B. type, each capable of giving 400 amperes at 93 volts. The dynamos are driven at about 700 revolutions a minute by two Marshall port-

Digitized by Google

able engines of 20 horse-power, and one Robey semi-portable engine of the same horse-power. These engines are capable of working up to about 180 horse-power, of which about 150 are usually utilised. The present engines and dynamos are merely in temporary use until the permanent machinery for lighting the Savoy Mansions, as well as the theatre, has been erected. They are at present placed in the basement of these mansions, which are now in course of construction.

A very convenient feature of the installation is the placing of the switch room on a corner of the stage, the whole of which it commands, so that the engineer-in-charge has no difficulty in knowing the exact moment when any set of lamps have to be raised or lowered, or when a change of colour has to be made.

The lamps in the auditorium are lowered when required by the introduction of resistance into their circuit in the ordinary manner, since there are other lamps on the same machine, and the introduction of a resistance into the shunt circuit would of course affect the whole of the lamps. Other groups of lamps which have to be raised or lowered separately are regulated in a similar manner.

The raising and lowering of the lamps is effected by means of four eight-way switches, so that the change can be made in as many stages.

The wiring is still as in the original installation, and it has been carried out in such a manner as completely to guard against all risk from fire. The main leads are nowhere allowed to cross, but are kept throughout at a considerable distance apart. When the installation was first carried out no safety fuses were used, as they had not then been invented; but these have since been inserted wherever a branch wire leaves the mains. They are of the ordinary pattern used by Messrs. Siemens, on earthenware bases, and no combustible material is used in their construction. No double-pole fuses are used, as Messrs. Siemens object to bringing the leads close together, which their employment necessitates; but in the engine room a fuse is placed on each of the main leads.

As is usual, there are pilot lamps in the engine room, carried on each of the circuits, which, in addition to assisting to light the room, keep the engineer informed as to whether the lights in the theatre are turned up or down, and whether everything is going on all right. No gas is used on the stage during performances, so that the principal element of danger in gas-lighted theatres is avoided, and though it is kept burning in the corridors, and a single jet is kept lighted in the dome of the auditorium, in case of a breakdown in the electric light, it is not at all likely to give rise to any danger of fire in these positions.

AN EXPERIMENTAL METHOD OF FINDING THE WORK EXPENDED IN ESTABLISHING A MAGNETIC FIELD.

The *Comptes Rendus* contains a note by M. A. Witz, in which is described an experimental method of determining the energy expended in establishing a magnetic field. It is known that if W be the work so expended, L the coefficient of self-induction of the circuit, and i the current at any time, we have for W the value

$$\int_0^t i \frac{d\,L\,i}{d\,t};$$

W can therefore be calculated if we know L; but this is not usually the case.

M. Witz's method of experiment is very simple. The solenoid containing a soft iron core is placed in parallel with a coil of the same resistance, but without self-induction. An ammeter is connected up with the latter, and a sensitive differential galvanometer is placed in circuit with the two branches. Upon closing the battery key we then get a throw of the galvanometer needle, although there is no steady deflection when the permanent state is reached. The solenoid is now removed and an equal resistance without self-induction is substituted. [This portion of the experiment is not fully described by the author, but we take it that the above is the method followed.] The resistance of this branch is now increased by an additional resistance r, and r is adjusted until on closing the circuit a throw of the same value as before is obtained. Knowing the current i in the branch, we know, therefore, the additional energy $i^2 r$ expended, and this is manifestly equal to the energy previously expended in magnetisation.

In order to determine whether the energy restored on demagnetisation was the same as that expended in magnetisation, M. Witz balances a solenoid as before against a non-inductive resistance with a differential galvanometer, and then allows a soft iron core to fall freely through the solenoid.

In describing the experiment M. Witz says that it can be assumed that the core comes from an infinite distance and is removed to an infinite distance, and under these conditions if the energy given up on demagnetisation is the same as that expended in the first instance there will be no deflection on the galvanometer. But such a deflection is always found, and, as might have been anticipated, it is greater with a solid than with a laminated core. But in addition to the loss in Foucault currents it is clear that unless the velocity of the core is uniform during the passage through the solenoid further errors will be introduced. The method does not, therefore, seem particularly well adapted to determine the question in view.

REVIEWS.

Voltaic Electricity. By Thomas P. Treglohan. (London: Longmans, Green and Co., 1888.)

In the year 1874 it appears that the South Kensington examiners in science required the students in the elementary stage of electricity to answer the question, "What is your notion of the voltaic current?" We will not stay to consider whether this was a fair question to ask an elementary student; but we may be sure that the replies received would be "considerably various." Whether any greater unanimity might be anticipated from students who have now the advantage of studying Mr. Treglohan's little book is doubtful, seeing that he is wise enough to abstain altogether from giving any "notion" upon the subject, either his own or other people's. Notwithstanding this omission, the book is well adapted to serve the purpose of those whose ambition is to acquire enough information to gain a South Kensington certificate. We note, by-the-bye, that the South Kensington teachers have not as yet abandoned the use of such terms as "tension" and "quantity."

Laxton's Price Book, 1888. (London: Kelly and Co.)

The present issue of "Laxton's Price Book" makes the seventy-first edition of this well-known annual, and contains above 72,000 prices. It is unnecessary to comment upon its value to architects, builders, engineers, and contractors, by whom it is accepted as fulfilling an essential requirement of their business. As regards the electrical industries the information furnished is confined to the retail prices of fittings or appliances for domestic use. Hence we have electric bells and fittings, including burglar alarms (fire alarms are omitted), telephones, and electric lighting. The information under each of these heads is accurate so far as it goes, but might, we think, be extended with advantage in some cases. In telephones, for instance, the class of apparatus specially designed for domestic or office use is conspicuous by its absence. The section on electric lighting must have been a difficult one to compile in a satisfactory form. It has, however, been well done, and will afford much useful information to would-be purchasers.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

ALTERNATE-CURRENT TRANSFORMERS.

The adjourned discussion on the papers by Mr. Kapp, Mr. Mackenzie, and Prof. Forbes was continued on Thursday, Feb. 23, Mr. Graves, the president, in the chair.

The President announced that some diagrams had been placed on the wall illustrating Prof. Ayrton's experiments described at the previous meeting, and

Mr. Lamb, one of the students of the Central Institution described the diagrams (Figs. 1 and 2) illustrating the experiments carried out by Prof. Ayrton (and described by him at the previous meeting) to determine the efficiency of the Kapp and Snell transformer. Fig. 1 represents the transformer enclosed in the calorimeter, by which the true watts were determined. There were also in circuit the wattmeter W, the dynamometer D, and the voltmeter V. The ratio between the reading of the wattmeter and the true watts was given last week by Prof. Ayrton (see *Electrician*, February 24th, p. 421*). The curve in Fig. 2 shows the true efficiency as calculated from the calorimeter observations, and also the values obtained from the wattmeter, and from the product of the readings of the dynamometer and the voltmeter.

* *See* also the report of the meeting of the Physical Society in the present issue.

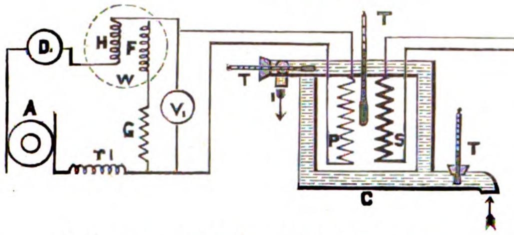
Mr. J. E. H. Gordon, while fully appreciating the scientific interest of these appliances, and the great practical use that had been made of them, could not help feeling that it was a pity to see so much ingenuity, so much skill, and so much labour lavished on what, in his opinion—possibly he might be wrong—could only be intended for a makeshift to enable them to go on until something better was ready. If he might be pardoned for putting into a scientific discussion a word of autobiography he might say he was not altogether incompetent to speak on the development of alternate-current machines, for he supposed few people had been so deeply committed to them as he had been, or had to do with the actual practice of such large ones; and yet, even at the expense of abandoning every patent that he held, he had been so far convinced of the superiority of the method of distribution by storage batteries that he preferred to abandon his own system. They had all heard with a thrill of interest and delight of the 42ft. machines. It was not quite a new thing to think of these machines, although it was a new thing to give an order for them. He had made sketches of one—in fact, had gone as far as the working drawings—about a year and a half ago, and he admitted he was much tempted to go on. It would be very delightful to have such a machine. It would be worth running a great deal of risk merely to see such a mass of machinery moving and going round above your head; but to quote a French expression, "*C'est magnifique, mais ce n'est pas la guerre*," which may perhaps be translated by saying that that delight would be more felt by the engineer than the shareholders.

Fig. 1.



A, Dynamo; C, Calorimeter; T T, Thermometers.
P and S, Primary and secondary coils.
D_1 and V_1, Dynamometer and voltmeter in primary circuit.
D_2 and V_2, Dynamometer and voltmeter in secondary circuit.
W, Wattmeter; H being thick wire coil, F suspended fine wire coil of 2·16 ohms, and G the stationery non-inductive resistance of 895·5 ohms in series with F.
r_1, Adjustable resistance in primary circuit.
r_2, Non-inductive resistance in secondary circuit.

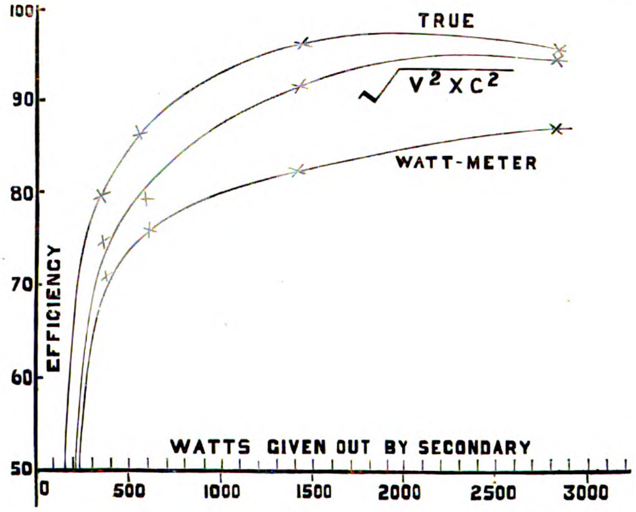


Fig. 2.

He was not speaking of the abandonment of alternate-current machines, nor was he speaking of them as if they had been failures, or as if they did not work economically. His alternate-current installation at Paddington had worked for two years, and was now working, and in one year they had supplied 800,000 units of electricity. It was supplied at a price that was extremely low, and which they should not shrink from. It was only from reasons which he would give in a moment—which he hoped would be convincing—that he thought storage batteries were better, not because alternate-current machines were bad, but because he thought there was something else better, and therefore he had determined to abandon them. The first consideration was the space occupied by these machines. They knew that experiments had been made for employing a number of small alternate-current machines, and that these experiments had been successful at the South Foreland; but that was because they were working with arc lamps. Many people had tried to work alternate machines in parallel, but they did not work together till they had jumped for three or four minutes. Now three or four minutes' jumping in the big machines might take a month's life out of 20,000 lamps, and that loss was rather a serious difficulty. Therefore they might take it in practice—he was not talking of what might be done in the laboratory—that they would not couple alternating machines, and that they must have very big machines if they were to get alternate currents to do the work. Those machines took up a dreadful amount of space. He did not think 10ft. diameter was an out-of-the-way size for a machine to give 200 to 250 units per hour, and that was what their Paddington machines were doing. Mr. Crompton was now making him machines with armatures 16in. in diameter, and two of these will do the same work as one of the 10-foot machines. If they had alternate-current machines they must practically be placed outside the town, and the wires and mains must be brought into the town. But with these modern direct-current machines, and with modern engines such as Mr. Willans was making for them, they could pack the machinery so close that they could get an immense power in a small place, and none of their neighbours were any the wiser. His company, the Whitehall Electric Supply Company, were, at this moment, putting in plant within a quarter of a mile of this place for 10,000 lights, and had room in the engine house to extend the supply to 20,000 lights. They were using an engine house 86ft. by 40ft. That included boilers, batteries, and everything else. It might be said that 20,000 lights were a drop in the cup in London lighting, and they had to face the question as to whether they were going to put up very large stations or make numerous stations of about 20,000 lights. They all knew that one of the advantages of central station lighting was the great economy in management and working that was obtained by increasing the number of lights from one station. But that increase did not go on indefinitely. Now, if they had got about 500 lights, they would find, roughly speaking, that the cost for wages in the 500-light plant would be about 10s. per lamp per year. When they went up to 10,000 lights, they would reduce that to perhaps 1s. 2d. per lamp per year. But after 20,000 lamps they did not get any further decrease in the wages, because they must have more machinery—they must have more room and more men, and it increased *pro rata*. Therefore there was no doubt an advantage in having more than one station to work more than 20,000 lamps. They had the further advantage that if there were a number of stations of from 10,000 to 20,000 lamps, and they were working with direct current, they could couple those stations together. One

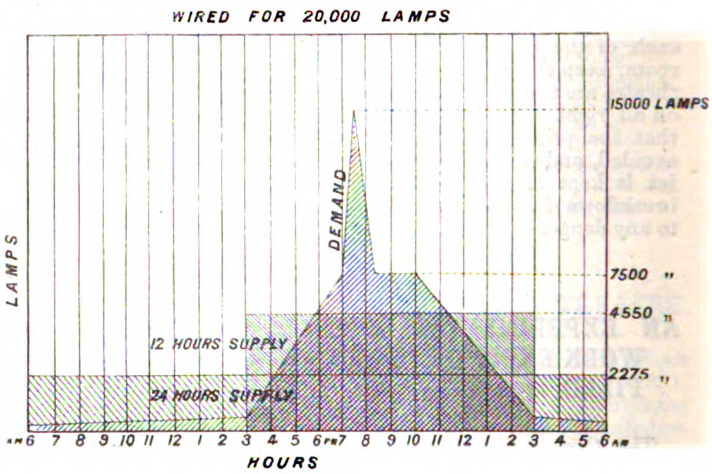

Fig. 3.

might be working at one end of a main, and one at another; and if anything went wrong at one station the other station could help it out. There were certain definite reasons which he thought would always make a number of small direct-current machines more economical in working than any big machines, and he would go somewhat briefly into it. The first was a reason which he could explain better by a diagram, which he had had placed on the wall (Fig. 3), showing the curve of output of current for a residential district and taken from actual figures. That diagram showed that the maximum demand was very much greater than the average. Hotel districts and club districts showed different curves. The diagram represented hours from six one morning to six the next morning. The vertical ordinates showed the number of lamps, and assuming that the installation was wired for 20,000, the number of lamps was small till about three o'clock, say, on a winter afternoon. Then it rose pretty steadily and regularly till about six o'clock. Then it went up in a rush. Then it came down and remained pretty nearly constant from about half-past eight till about ten. That was the time when the first batch of people went to bed. Then it sank gradually. There was apparently a great line of virtue about ten o'clock. People who stayed up after ten o'clock seemed to be reckless of hours of morality, and merely dropped off one by one until the morning. The reason of the rise between seven and half-past was rather curious. That was the time when people went up stairs to dress for dinner. About the same time the servants are laying the cloth in the dining room. So it happened that that was the only time that the lights in the dining room and the bed rooms were lit at the same time. That sent the current up with a rush. Assuming that they were working with an alternate-current machine, with 20,000 lights wired, and they had, say, 15,000 lamps in use, in order that there should not be a breakdown they must have their machine powerful enough for 15,000, and that meant not only that the alternate-current machine, but that the engine, boilors, dynamo, and engine house must all be up to that size. Assume also that they were supplying by a contract based on meter. It would then be evident that a great portion of the machine was only earning money for an hour and a-half in the 24 hours,

Digitized by Google

and that half the power of the machine was wasted for at least 12 hours out of the 24. But the interest on the cost of the machine was going on for the whole 24. Now let them see what would happen if they had storage batteries. Assume first of all that they were going to have a moderate amount of storage, and would work their machines for 12 hours. The quantity of electricity for the day was shown by the area of the demand curve; that showed the number of units—and the area of this second curve, or 12 hours' supply, must be the same as the area of this other curve, showing the quantity required for the day. If they had storage and worked their engines for 12 hours, the maximum current need only be a current for 4,550 lamps. The size of the engines, burners, and boilers was fixed by that. Therefore, for 20,000 lamps, with an occasional supply of 15,000 at once, it was not necessary to have, by storage, machinery of greater capacity than 4,550. If, however, they decided to work their engines for 24 hours—which might in some circumstances be advisable—they could then have something much smaller still. He supposed in practice, what they would do in designing a new installation would be to so arrange that the engines, when they are first put down, are to work twelve hours to meet the demand, and then as custom comes in they could decide according to circumstances whether they would increase their engine power, or whether they would increase their battery power and work longer hours. But probably they would commence working twelve hours and increase the hours of working as custom came in. He must further point out that whatever percentage loss there might be in the storage batteries must be calculated not on the whole area of the curve, but only on those portions of the supply and demand curve which do not overlap - a very different thing. That dealt with the capital cost of the plant. The next point was the efficiency of the dynamo. Mr. Mackenzie knew perhaps even better than he himself did that the efficiency of the alternate-current dynamo was quite different when it was fully loaded from what it was when not loaded, and the alternate-current dynamo that would give, say, 4,000 horse-power a day, and give a very good efficiency, say 90 per cent., or whatever it might be, would not have anything like that efficiency when the dynamo was working at a half or a third or a quarter of its power. There was, however, a much more important point than that. The alternate current machines, whether used direct, as was their practice in Paddington, or when used in these transformers, required for their successful adoption that the number of alternations per second should be sensibly constant—that is, they must not greatly vary the speed of the engines and the speed of the dynamos. They must run their engines at very nearly the same speed whether they were giving their full power or whether they were giving only a fraction of their power. He would ask them what the diagram of a quadruple expansion engine of 5,000 horse-power would be, working at full speed at 1,500 horse-power? Probably two cylinders would be working one way, and pulling the other two round, and the diagram would be of a somewhat peculiar nature. Experience showed that a compound engine, working at full speed at a third of its power, burnt at least twice as much coal per horse-power as when it was working at its full power. Now, these smaller engines that were used for storage current might be easily coupled together. They worked their engines at their full power until they had obtained the storage they wanted, and then they stopped. The engines were either worked at their full power or were stopped. Therefore they were bound to get a far better economy than could be obtained by working big compound engines at half their power. There was another reason for scattering stations, and placing them where you could use engines that would not be a nuisance in great populous districts. London was now being filled with great buildings, residential flats, great hotels, and buildings of that sort, and the best site of a station was somewhere near one of these, where they could use their lamps to begin with, as there they could for the first time meet the gas companies on their own ground, and utilise *waste products*. At Whitehall he had taken a contract to sell a quantity of hot water day by day that would use up the whole of his waste steam, and thus what was formerly an expensive nuisance was converted into an important source of revenue. He did not, however, wish to be too precipitate in his condemnation of the transformer. These were two systems, both endeavouring to do their work as best they knew. He felt that his friend Mr. Mackenzie was doing good work in educating the public to the use of electric light, and persuading them to wire their houses. Mr. Mackenzie's customers would, he hoped, then transfer their custom to him on seeing the advantages of the storage system. Perhaps they must not allude to it too particularly, but they might remember that there was yet a third system of electrical distribution which they had heard of a great deal within the last few weeks, which he thought none of them would wish to assist more than they could, and that was the system of distributing electricity from house to house by means of circulars.

Mr. Crompton said they were discussing two papers on transformers, and he thought his friend Mr. Gordon had rather wandered away from the subject. He hoped they would check him if he wandered away in the same direction, because there was a great tendency to do so. The subject of transformers, taken by itself, viewed more particularly from the side Mr. Kapp had viewed it, was of a somewhat dry nature, and they would, he hoped, excuse him if he tried to infuse a little more liveliness into the discussion. The lighting of the future, so far as they knew at this present moment, was going to be handed over to the one system or the other, to battery transformers or to alternate-current transformers. He considered that the questions that these papers had raised at the present moment were of supreme importance. The company that he had been more particularly speaking of—for which they had the highest respect—the Grosvenor Gallery people, had done a very great work, and he thanked them most heartily for educating the people of London to like the electric light. They were showing how people would put up with any sort of light. It was very difficult to follow a very good man over his ground, but it was very much easier to beat a man who was not quite so good, and in that case he thought the Grosvenor Gallery gentlemen would excuse him if he said that they had a little to learn still in the way of producing the electric light. Hitherto they had produced scintillations which were not altogether pleasant to people who were sitting at five o'clock tea in a Mayfair drawing room. He believed that Mr. Mackenzie had explained many of the causes of these things, which of course they must not laugh at; but as an opponent he took advantage of them, because he believed they were inherent in the system. He believed that with the alternating transformer system, as at present arranged, they were very greatly dependent on what their neighbour did, and that accidents to their neighbour's transformer affected an innocent person several blocks off in a way that could not happen with the direct system by distribution carried on from a series of accumulating or storage centres. He had long had the two systems before him, and he had been working at the subject for the last two or three years. As most of them knew, he had carried out central stations in which the transformation from high-tension currents of 500 volts had been carried down to 100 volts, usually employed in incandescent lamps by means of four batteries in series. He had data from these installations, and data which were of use. It was no use in such a place as that to discuss the question of management—that is to say, wages and matters of that kind—but it was of great use to discuss the scientific engineering part of it, that is, the question of which system worked with the least horse-power, which worked with the least first cost in machinery, the least first cost in mains, and the greatest steadiness and regularity and freedom from breaks down. From these points of view he proposed to compare the system of alternating transformers with the system of battery transformers. At this stage he would remind them of the tremendous leg-up which the alternating transformer system had received from Mr. Westinghouse. Westinghouse was one of the most wonderful men in the world. There was no man like him as an organiser of labour and as an organiser of machinery. Witness his brake. In the face of the most tremendous opposition from the railway authorities he had made his brake almost universal, and he had done that with all these peculiar powers. He was a very rich man, and he had unexampled facilities at the town of Pittsburg, where his most successful lighting had been carried out. But he would tell them that what Westinghouse had done for the transformer system was exactly what Brush did for arc lighting when they used arc lighting—they might say for the first time—in England a few years ago. He had turned out from a well-appointed factory complete, well-considered sets of machinery, packed and sent away to any township in America that wanted electric light of a sort. It could be put up in the way that American electric lighting machinery was done—very roughly—on the spot. But the things were so well appointed and so well made in the factory, that they could be erected at small cost, and in sufficiently good rough and ready fashion to suit the American taste. Anybody who had been in America, anybody who knew anything about American installations would confirm what he was saying—that electric lighting machinery in America as made in the shops was perfection; but the putting of it up was such as would not pass muster in the worst of our English installations. That had been the case with the enormous list of transformer machinery that had been carried out by Mr. Westinghouse. Although that was perfectly suited for such countries as America and Australia, countries where rough workmanship and such things did, it was quite unsuited for civilised countries. The alternate-current transformer was well suited for such cases, but the moment they brought it into London, the moment that it was no longer a rover, as it was at present, over the tops of the houses, the moment they confined it under the streets, then it lost all its advantages. What were its advantages? Its advantages were that they could put down a station, and they could run wires anywhere they pleased, on account of the peculiar state of the law, and take up a number of customers that otherwise they could not reach at all. But he said that when the taste for electric lighting became more universal, when two in every three people along the line of streets took the light—that such a system of overhead mains and that kind of thing was intolerable; and there must come the day when mains had to be laid, as they had been successfully laid under the streets, and then they would find that the alternate transformer system was out of it as compared with the other. He was glad to see that Mr. Kapp, in his paper, practically admitted that. He admitted it in his last sentence, and a man puts his sense in the last sentence of his paper. The fact of the matter was, when Mr. Kapp said they would have to lay down a network, and when Mr. Mackenzie said they would have to lay down a network, he would like to know in what way they would lay down a network cheaper than the batteries. The mains could be laid in the streets from 14s. at the lowest to 16s. or 18s. a yard at the highest. The smallest section of copper could not be put in under 14s., and 16s. or 18s. would give them a very fair section of copper quite sufficient for an ordinary length of streets. When people talked of copper as if copper were the only thing that had to do with the cost of conduction, they were talking nonsense.

This was not the place to go into a long comparative estimate as to the cost of the two systems; suffice it to say, he had figures in his possession that he had worked out very carefully. He would not take the extreme figures mentioned by Mr. Mackenzie, who assumed 100 volts and transmitted it through an inch and a-half cable with 1,500 amperes at 100 volts potential. By taking 500 volts, which was workable for a distance where the generating station was situate from a mile to two miles from the centre of the district to be supplied, the cost of the two systems works out practically identical. That was to say, if 10,000 lights had to be supplied in a town, with the generating station situate not more than two miles from the centre of the supply, the cost of those 10,000 lights—and he called the maximum number at one time 10,000 lights—the cost was identical in the two cases, and there was no saving by using the alternate system.

Digitized by Google

Now, he would attack the alternating system as an efficient one. They had heard a lot about the efficiency of transformers. There had been a fight over a few places of decimals. That was whether they were 80 or 90 per cent. They had got efficiencies showing that at a very low heat indeed the true efficiency was as high as 80 per cent. of the transformer, and he did not believe that. The large transformers that would have to be large enough to go up to the peak of the diagram shown by Mr. Gordon, but when they were working in the day time, they would not be working at much more than 15 to 20 per cent. efficiency. Further than that, those transformers were worked by very large dynamos. Mr. Mackenzie talked about 42ft. 5,000 horse-power dynamos, and they were told that the total size of the station was 20,000 horse-power. He would like to know how many tons of coal per lamp (laughter) it would take to work those lamps at the day-time. He had made some experiments in this direction, and he knew from experience in years gone by, and from later experience, what it meant to run engines, even with continuous currents, without the aid of batteries, *i e.*, to run them nearly empty. There was not a more extravagant beast on the face of the earth than a compound or triple expansion engine worked down to a fourth or a fifth of its full output. As Mr. Gordon said, the two other cylinders were nothing more nor less than air pumps—drags on the engine, and Mr. Willans could tell them a great deal better than he could what they would do. They might put it in this way: These big engines used about two-thirds of the coal when empty that they did when full—that is to say, if using 20 tons a day when full, when they were running one lamp they would be using about thirteen or fourteen. So they could seen what it came to. Everybody who worked central stations knew these facts Mr. Mackenzie knew them He knew how much coal they were burning now at the Grosvenor Gallery, and he (Mr. Crompton) knew, and he could tell them they were burning five times as much coal at the Grosvenor Gallery, lamp for lamp, as he burnt at Vienna. That was because *he* employed accumulators, and *they* were wasting their coal by having to keep a big engine running for long hours when there were very few lamps on. If Sir Coutts Lindsay had asked him to put up a battery system about two years ago, Sir Coutts would have saved enough money in his coal bill from the time he started to pay for two new batteries. Mr. Gordon's diagram was almost an exact copy of half-a-dozen diagrams that had been shown to himself this evening by Dr. Fleming, which had come from the Edison Company in America, and referred to various installations. That diagram of Mr. Gordon's, which he knew was founded on London experience, was almost a correlation of work that he had done at Vienna, and it was exactly corroborated by those most interesting diagrams that Dr. Fleming had got, which pointed out that there were peaks for only an hour or a couple of hours' duration, when the demand was nearly double that of the other maximum demand—he meant by the latter the demand that lasted for three or four hours—and something like 10 or 12 times the average demand. He thought the whole pith of the economical question lay in studying diagrams of this kind. The whole thing was turning on the one question that was raised by Mr. Mackenzie. Mr. Mackenzie had thrown doubt on the question which had been over and over again asserted, that they could not run alternate-current machines in parallel. If they *could* run them parallel, that would knock the bottom out of a great many of his (Mr. Crompton's) arguments. There was no doubt about that. But it had not yet been done—he had taken very great pains to find out whether it had been done in practice—but it certainly had not been done here in England, and it had not been done in America otherwise than experimentally. When these gentlemen could use them so that they could follow the lines he did of putting one dynamo on after another, and working them up to their full capacity and their best efficiency as the demand arose, and fill up the sharp angles between the dynamos by working accumulators in parallel to them—till these gentlemen could do that they would never approach the efficiency that he had at present. He believed from Mr. Mackenzie's statements and from all the rest he could hear, that Signor Ferranti had virtually admitted that they could not put the machines parallel by his desire to construct these gigantic machines that were mentioned in the paper.

Mr. Esson said that coming after a most energetic representative of the anti-transformer party he wished to express his indebtedness to Mr. Kapp for his most interesting and instructive paper. In dealing with this problem Mr. Kapp had introduced the graphic method, which was always a great boon to the engineer, inasmuch as he could see at a glance what had taken place, and was able also to apprehend better the modifications in results obtained by the modifications in proportioning. Throughout his investigations, however, Mr. Kapp assumed that the electromotive force impressed in the primary, or rather the electromotive force generated by the dynamo was a sine function of the time. But surely in modern machines, with iron cores in their armatures, that was not quite the case. He could believe that in a Siemens dynamo the curve would be a sine function, and also in a Ferranti dynamo the deviation might not be great, but in a dynamo having an iron core in its armature, he could say most decidedly it would not be a sine function, nor would it be anything approximating to a sine function. He had endeavoured to map out the magnetic field in a dynamo something like Mr. Kapp's own design, where they had a disc armature with sets of poles on each side. The result, so far as he could make out, was shown by the diagram skied to the right, where A (Fig. 4) is the curve of sines, and B is the curve got from the dynamo. They would see the flat part in the middle. That part might be a little too long in the diagram, but its length depended entirely on the construction and the proportions. He did not say that the deviations detracted from Mr. Kapp's method, but they certainly modified the results he had obtained both in the mathematical and the geometrical treatment. One must, of course, assume something as a basis in the absence of experimental data. Mr. Kapp assumed the curve of sines, and the question arose, how much the results were modified by deviation from that curve? His own view was that no true result could be obtained without actual experiment.

The point regarding the degree to which the core of the transformers could be saturated was most interesting. From Mr. Kapp's investigations it seemed that the number of C. G. S. lines was only one-half of what could be employed in the armature of a continuous current dynamo. He would like Mr. Kapp to state what was the usual weight of transformer per 60-watt lamp, and also how many volts he got per foot of conductor. In the Westinghouse transformer, he believed, they got 2 volts per foot. There seemed to be very little difference in the construction of the transformers, excepting that the object in some cases appeared to be variation rather than an improvement. He thought the transformer of Mr. Kapp had an advantage over others, inasmuch as it could be taken to pieces. They had simply to take the cover off it, take the coils off, and slip a fresh pair on. Taking the whole arrangement to pieces, as they had to do when they had the iron parts interlacing with the copper parts, might be sometimes rather inconvenient.

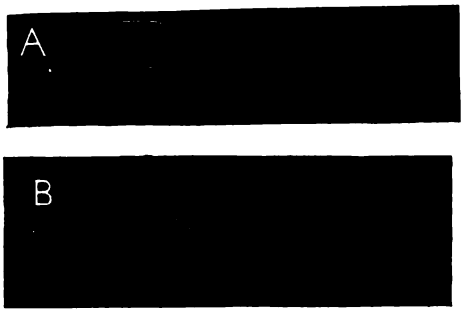

Fig. 4.

Leaving transformers and coming to the distribution, it seemed that here there was some little room for discussion. He understood Mr. Bernstein to advocate the series system, and in his paper Mr. Mackenzie showed himself rather favourably disposed towards it. It appeared that putting a constant current in the primary they had a current which was practically constant in the secondary, and therefore the arrangement was admirably adapted for lighting lamps in series. So far, then, as self-regulation went, there was no difference between the two systems; but when they came to the question of cost he thought that the conductors would cost more, in any case, in the series system than it would in the parallel system. They had to keep the same section of conductor right through the system. If they had to go down 100 yards to light a single lamp they would still carry a heavy conductor with them wherever they went; and although Mr. Kapp said that in sparsely populated districts the cost would be less, he himself could not quite make out how it was. As regarded the dynamo of Mr. Kingdon, he did not think very much of it, and for the reason already referred to by Mr. Atkinson. The magnetic circuit should not be subject to constant changes in section as the machine is working, otherwise Foucault currents would be induced in the magnet. He prophesied that the machine would get hot. He would be very glad to learn that it was not so; but if it was not so it could only be by laminating the field, which he was afraid would be rather expensive. In conclusion, he had been very much puzzled by the last sentence in Mr. Kapp's paper. He was not quite sure whether it was intended to be prophetic or not. If Mr. Kapp thought that they really would get batteries sufficiently improved to render lighting by continuous currents possible in the future, it would be a great pity, though having the conductors all right, to find at the generating station that he had his dynamos of the wrong kind, and that the transformers were also useless. He therefore advised Mr. Kapp to give up the alternate-current system, to put in at the generating station high-tension dynamos, and to use continuous current transformers at the sub-stations. He would then be ready, on the contingency of a good battery arising, to supply by storage. He could either charge his accumulators direct from the central station, he could charge them through his transformers, or work the lamps from the transformers. He (the speaker) did not say that the system of working with a continuous current transformer would be quite of such high efficiency as the alternating transformer system. Neither would it be so low as working from accumulators, as Mr. Crompton advised, but it would be somewhere between the two, and the accumulators would be simply used as a stand-by. They would be charged occasionally, just to make up the leakage.

Mr. Sidney Evershed said that Mr. Esson had anticipated a few of his remarks in his protest against the importance of the sine function. There was one very good reason for employing it, however, and that was that it was the only one which could be worked mathematically. It was rather remarkable that the sine function was, so far as he could see, the only one which was reversible—that was to say, that the secondary current would also be a sine function of the time. According to Mr. Crompton's view, the sense of the paper was in the end, and, therefore, perhaps the sentence was really nonsense where Mr. Kapp said he had reason to think that a curve of electromotive force, of whatever shape, produced by the machine would, after filtering through two or three transformers, come out as a true sine curve. Of course, Mr. Kapp, with his beautiful geometrical method, hoped that it would come out as a true sine curve; but he was himself afraid that the facts were against Mr. Kapp. He thought the effect of filtering it through one transformer—and one would be all-sufficient—if the original curve departed in any way from the sine curve, the effect

Digitized by Google

would be to make it depart still more from the sine curve. However, that as Mr. Esson said, did not detract from the merits of Mr. Kapp's paper in the least, nor from his method; but it did in some measure detract from the interest of the results obtained, because if the sine function was not a true one, what became of all the results Mr. Kapp arrived at—such as the power spent in a transformer being equal to the virtual E.M.F. into the virtual current, into the cosine of the angle of lag? Mr. Esson had been good enough to give the meeting a diagram of one curve, which showed what a complicated function a modern dynamo might give. The Westinghouse dynamo was also supposed to give—not a sine curve, but something like a zigzag of straight lines. The only way he could see of attacking that problem was to assume that it was a hyperbolic function; but he could only echo Mr. Kapp's wish that some one with the necessary mathematical attainments would investigate the subject.

He should like to say a word or two about the wattmeter for measuring power. Dr. Fleming described a large wattmeter which apparently gave very inaccurate results. There was really no need for a wattmeter to be large. If Dr. Fleming were to make a wattmeter like those beautiful instruments which he showed at the meeting last year, and employ a few ampere turns—say, two or three on the pressure coil, and a large number, 100 or so, on the current coil—they would have an instrument in which there was practically no lag in the pressure coil, and consequently it would give the mean of the true instantaneous watts. He had made a wattmeter which worked very well indeed with about 100 ampere-turns in the current coil and about five ampere turns in the pressure coil; and he imagined Mr. Kapp would not object to five ampere turns, when they remembered that in an ordinary incandescent lamp there might be perhaps one ampere-turn, and it was customary to neglect the self-induction of one lamp.

Prof. PERRY said he should like to say a word or two upon this matter of the sine curve. It had been said by Mr. Esson and by Mr. Evershed that the curve was not a true sine curve, and therefore that Mr. Kapp's theory must be wrong. Before, in that room, he had made a correction of such statements. He understood that Mr. Esson measured his field—the field of the dynamo machine—to get this particular curve. If they got Mr. Esson's curve for the field, then the current—the primary current—would obey very nearly the sine law, and the law of the secondary from the transformer got nearer to a sine function still. The effect of self-induction and mutual induction was that they took out the minor ripples. A curve like that of Mr. Esson's was built up in this way, of several sine curves of different periods [illustrating on the blackboard]. A combination of one sine curve and its harmonics would give the curious curve that Mr. Esson described. They found that if they had one sine function of a certain period, another of twice that period, and others three times that period, they could get exactly what the effect of self-induction was in toning down the ripples or the harmonics. They found that they were toned down tremendously. It depended on the self-induction. All those ripples were toned down, and the quicker ripples toned down very much more rapidly than the slower ripples in passing through the transformer, and he did not think it was possible by any method of measurement to get anything very different from a true sine curve in the secondary current. The time was very late, but it would not take him more than two minutes to mention to the meeting something that suggested itself to Prof. Ayrton and himself some time ago with regard to an instrument for measuring the actual way in which the current does change. Mr. Esson, Mr. Evershed, and others had said that there was not a true sine curve. Well, then, there was a way of testing it, and the way of testing it would be this:—Not only was this a beautiful investigation in itself, but any person carrying it out must become familiar with Fourier's method of analysis and impressed with its beauty. It was like Helmholtz's method of analysing a sound by resonators. Let them take a dynamometer, and send the alternating current through the thick wire coil only. Then let them take the fine wire coil, and have a little battery with a make and break, and let that make and break be controlled in some way so that they could readily vary the rate of vibration—the rate of vibration, say, of some tuning fork. Let it be varied, so that they could measure the rate of the make and break. The main current might have any amount of ripples in it that they liked to assume. Now when the rate of alternation in the fine wire coil reached the fundamental rate of alternation in the current coil, and then only, they would have attraction between one coil and the other. If the main current had no other rate of alternation than that, according to Fourier's theorem they would have no action of the one coil on the other, except at that one rate of vibration. So that by changing gradually their make and break—changing it to quick from slow—they looked out for an indication. And when their readings on this instrument were greatest, when they knew they had got the alternation of the main wave—the main alternation of the current—they had got their main wave then, but they had not got any of the ripples. They now continued to quicken their make and break, made it quicker and quicker, and when they got to twice the rate of vibration they would probably see some indication. If it was small it meant a small ripple of twice the ordinary alternation rate. Well, let them measure what it was, then go quicker and quicker till they got about three times the first speed. They would probably get another indication. Probably there was some period which had a pretty big effect. If he was right, however, in what he had been saying about the toning down of the ripples, they would not get much indication at any other speed than the one speed which indicated the main wave. It was easy to take the results and combine the measured fundamental wave with its measured harmonics, to find the real shape of the current function. It would be known to members that if the coils were at right angles to one another mutual induction would vanish and no error could arise from this cause.

THE BATTLE OF THE TRANSFORMERS.

The discussion on the papers of Messrs. KAPP, FORBES and MACKENZIE, which was brought to a close at the meeting of the Society of Telegraph-Engineers and Electricians yesterday week, has traversed so wide a field, and has been concerned with matters of such pressing importance to the electrical engineer, that it can hardly fail to exert a considerable, and, we think, a beneficial influence on the progress of central station lighting in this country. We say this advisedly, for though at the first glance it might seem that the chief result had been to show that the leading electrical engineers are at loggerheads amongst themselves as to the rival merits of battery transformers and alternate-current transformers, yet in reality the altercation arises from the fact that upon the whole the merits of the two schemes are very evenly balanced. Each of the contending parties has a sound and practical system to back up, each method has its own special advantages and its own special disadvantages, and time alone can show which of the two is fittest to survive upon the largest scale, or whether they are each doomed to fall before a system combining the merits and avoiding the demerits of all others.

Meantime it may be useful to take a hasty glance over the field of battle and to notice some, at least, of the chief points made by either of the contending parties. The partisans of the storage battery method gained an advantage at the outset by putting forward a champion in the person of Mr. J. E. H. GORDON, whose chief title to distinction as an advocate of the battery lies in the fact that he is a recent recruit from the enemy's camp. Mr. GORDON, with all the fervour of a new convert, offered a public recantation of the views which he had long been known to hold, and recited his profession of faith in the storage battery—qualifying his observations, however, by the remark that he had changed his views, not because alternate currents were bad in themselves, but because storage batteries were better. It is true that Mr. GORDON has carried out one of the very largest installations worked by alternate currents in this or any other country, but inasmuch as the use of transformers was not included in the scheme, it must be admitted that from our present standpoint his system involved all the disadvantages of alternating currents with-

Digitized by Google

out any of the advantages of the method under discussion. Besides, no one nowadays (almost certainly not Mr. GORDON himself) would place unlaminated iron in the armature of an alternate-current machine, no one would use the method of regulation known as the "divided-main system," and, in fact, no one would dream of using alternating currents at all, except for the purpose of being able to employ transformers.

Mr. R. E. CROMPTON speaks from the vantage ground of one who has had positive experience of the system which he advocates, and his remarks deserve, as they will undoubtedly receive, the most careful consideration. The point upon which Mr. CROMPTON chiefly laid stress—and certainly not undue stress—is, that with batteries it is possible to spread the work of the engines over as a long a period within the twenty-four hours as may be found convenient; so as at all times to work the engines at full power. When, on the other hand, the supply is taken direct from the machines, the engines must at each moment develop whatever power may then be under demand. It is well known—though the fact is too frequently lost sight of—that with modern triple expansion engines, such as could most advantageously be used for large central stations, the coal burnt per indicated horse-power increases rapidly as the output is diminished. This becomes a most serious consideration when the hourly curve of output of current takes such a form as was shown in the diagram exhibited by Mr. GORDON (and which will be found in our report of the discussion in the present issue). In this case the maximum demand is ten or twelve times the mean daily average, and lasts only half an hour or so. It would, however, be very misleading to generalise from a single diagram of this description. The particular curve exhibited referred, as we understand, to a district exclusively occupied by private residents, the peak in the curve occurring at the time when people are dressing for dinner, while the servants are at the same time busy in the kitchen and the dining rooms, so that nearly all the lamps in the house are for a short time alight. But, as Mr. KAPP pointed out in his reply, it is rare that an exclusively residential district would be served from a central station, and a comparatively small number of shops, clubs, or hotels would materially alter the shape of the figure. We think, however, that the speaker is justified in preferring the use of batteries in cases where the curve of the output takes such a form as was here shown. Mr. CROMPTON was, however, careful to say that his argument was based upon the belief—after careful inquiry into the facts —that alternating machines could not be run in parallel as a matter of practical everyday working. Of course every one knows that two such machines, if driven from the same countershaft, or run at approximately the same speed, will, when joined in parallel, presently fall into step, and work in perfect harmony; yet inasmuch as the automatic process may take a minute or two to complete itself, it is not applicable to central station work. But, as Mr. MORDEY pointed out, Mr. CROMPTON is wrong in supposing that the difficulty cannot be overcome. Mr. MORDEY mentions a case where two machines are worked in parallel upon opposite sides of a river. The Westinghouse Company do the same thing in Pittsburgh; although, seeing that this company does not usually adopt this method of working, it is perhaps fair to presume that they are not entirely satisfied with the results at present obtained. We may note in passing that Mr. CROMPTON conceded too much to his opponents when he said that "the bottom would be knocked out of his argument whenever it was shown that alternate-current machines would run in parallel." The argument as to steam power holds good whether the engines are employed to drive one large or several small machines.

One piece of information we vainly waited for in Mr. CROMPTON'S speech. We were hoping to hear something about the efficiency of the battery which he is using for central station work; but on this vitally important point nothing transpired.

It was probably rather a revelation for many people to find the Brush Corporation, represented by Mr. MORDEY, declaring strongly in favour of alternating currents. Outdoing the author of the paper, he prefers, so far as possible, to abolish low-tension distributing mains altogether, and, if necessary, to place several transformers in different parts of the same building, for the reason that it is cheaper and simpler to network the high-tension than the low-tension mains. Mr. KAPP, on the other hand, would employ as few transformers as possible, and establish sub-stations from which distribution might be effected by an Edison network. The latter scheme, as the author points out, has the advantage of being readily convertible into a battery-transformer system whenever batteries have proved themselves beyond all doubt to be reliable and economical appliances for the transformation of potential.

Meanwhile, taking into consideration the difference in the first cost of batteries and alternate-current transformers, the enormous advantage of the latter in respect of depreciation, and the difference in the cost of mains represented by the ratio of 2,000 to 500 volts (in the most favourable case for the battery), it is difficult to believe that batteries can as yet compete with alternate-current transformers from an economical standpoint.

OVERHEAD CIRCUITS FOR LONG-DISTANCE TELEPHONY.*

BY M. J. BANNEUX (CHIEF ENGINEER OF THE BELGIAN TELEGRAPHS).

For long-distance telephony a metallic circuit is an absolute necessity, as with a single wire and an earth return it is impossible to avoid the noises due—first, to earth currents; second, to induction from neighbouring wires; third, to the "picking up" of the currents from other circuits in the vicinity working also with earth returns. As an example of the last the author mentions an overhead wire in Brussels which made earth some fifty yards from a Morse instrument. The two wires ran at right angles to each other, so that there could be no appreciable induction between them, yet every Morse signal could be heard on the telephone line. Again, when M. Van Rysselberghe was superintending from Ostend to Dover, the operator at the former place heard a third voice joining in the conversation, which turned out to come from the Observatory, Brussels, from which a single wire runs to Ostend. The operator at Brussels had heard and answered the voice from Dover, though the only connection between the two lines was that they were connected to the same earth plate at Ostend. Besides this picking up of stray currents, there are other difficulties. Leaving self-induction and capacity on one side, the most troublesome are leakage and induction from other wires. In wet or foggy weather if a telephone and telegraph wire have even *one* post in common, it is sufficient to make the Morse signals audible in the other wire.

The best means of stopping cross-talk, due to leakage, is, the author considers, the English method of fusing good insulators and joining all their iron supports to an earth-wire at each post; most of the leakage current then gets to earth instead of into the other wires.

Induction from wire to wire is the other *bête noire* of telephonists, and to it many operators attribute cross-talk, which is really due to leakage. It is true, however, that in our foggy climates it is very difficult to determine which is the real offender.

The effect of one wire on another is represented approximately by the formula $m = 2l\left(\log_e \frac{2l}{d} - 1\right)$, where m is the coefficient of mutual induction, l the length of the two wires running parallel, and d their distance apart.

Although telephonic and telegraphic induction are of the same nature, it will be well to treat of them separately on account of the different means which must be taken to remedy them.

* Abstract of paper read before the Belgian Society of Electricians.

Digitized by Google

Every Morse signal, for example, gives two currents in a neighbouring telephone wire, the one reverse on making, and the other direct on breaking, and therefore two "clicks" on the telephone. Anyone who can read by sound can receive as well on that telephone line as if he had a sounder before him. If a Hughes instrument is employed the effect on the telephone is still greater, as the currents in the Hughes rise and fall more sharply, while an "automatic" is worst of all. A single Morse wire running parallel for only a short distance will make conversation difficult, so it may be easily imagined that conversation on a single wire is not only difficult but impossible when this wire runs any length along a railway, close to a number of Morse-speaking, signal-repeating, bell and other wires in continual action. The voice is completely drowned in a shrill fizzle of induced currents. The experiments made in 1883 between New York and Chicago, a distance of about 950 miles, on a single steel-copper telegraph wire, show that with a suitable conductor it

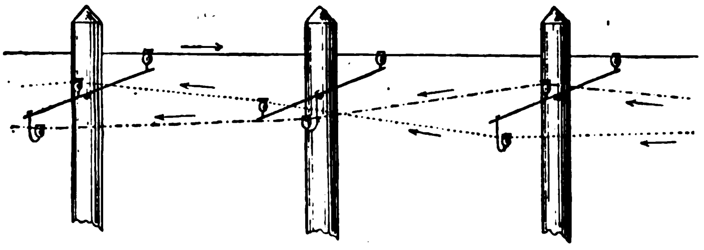

Fig. 1.

is possible to work over long distances. This, however, was only when the other wires on the line were not in use.

As to telephonic induction, if two single wire lines run parallel on the same posts for a few miles conversation on the one line is perfectly audible on the other; hence, if the exchanges of two towns are to be joined by earth return trunk wires, only one wire must be run on each line of poles. It may be asked how it is that in other countries comparatively long lines are worked with earth returns. In point of fact, it is impossible to talk to any one on these lines without taking some third party into one's confidence. When an American exchange manager was asked how they got over the cross-talk difficulty, "Oh," he said, "we just advise our subscribers to take no notice of what is going on on other wires."

We may note in passing that no advantage is to be gained by crossing earth return wires; induction always takes place, except between wires exactly at right angles.

Prof. Thompson has proposed making the transmitter ten times more powerful and the receiver proportionately weaker. This would, theoretically (leaving leakage out of account), give the voice equally loud in the receiver and diminish the effect of telegraphic induction to one-tenth. It would, however, have no effect in reducing *telephonic* induction. To the best of the author's knowledge there is only one practical system of preventing the telegraph wires having any action on neighbouring telephone wires—that of Van Rysselberghe. By this, as is well known, the makes and breaks of the telegraph signals are lengthened to such an extent that they have no appreciable effect on a telephone. This gets over the difficulty of telegraphic induction only, not telephonic. The general solution of the difficulty of induction, whatever may be the inducing causes, is to use two wires in a complete metallic

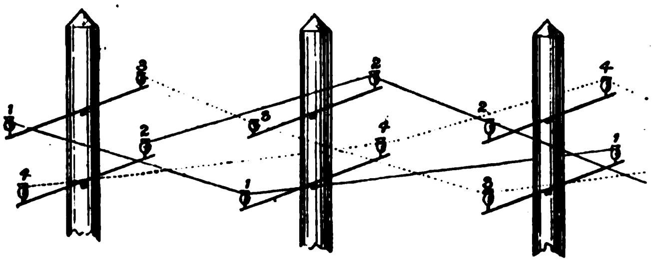

Fig. 2

loop instead of a single wire and an earth return, and to so arrange them that the sum of the inductions of neighbouring telegraph or telephone wires shall be exactly the same on both the wires of the loop. This principle was patented by Bell in 1877, and its efficacy was proved by Hughes in 1879.*

It was applied by Brooks, of Philadelphia, to cables, by twisting the two wires of the loop together.

If a line of poles only carries one telegraph wire and a looped telephone wire it is very easy to obtain equal induction on both wires of the loop; all that is necessary is to run the telegraph wire parallel to its neighbours and equidistant from both of them. The telegraph wires, however, in practice are numerous, and vary in number from section to section, and the telephone wires cannot be arranged so as to be equidistant from each particular telegraph wire. In this case it is necessary to adopt a method similar to that employed for cables, namely, to twist the wires together in long helices. Prof. Hughes suggested a plan for doing this in 1879, which was carried out by Messrs. Moseley and Sons near Manchester. Since 1881 the English Post Office have used the wiring shown in Fig. 1 for the trunk wires for joining two towns. If two trunks have to be run on the same line of poles they are arranged as in Fig. 2. Galvanised iron lines on this system are at work between Manchester and Liverpool, 30 miles; Newport and Cardiff, 13 miles; Glasgow and Greenock, 25 miles; Glasgow and Edinbro', 36 miles; London and Brighton, 54 miles, &c., &c.

In June and July, 1883, the Belgian Government established communication between Antwerp and Brussels, which towns, by the way, were the first two on the Continent which were joined by the telegraph in 1846. The trunk was run along the railways, using No. 16 S.W.G. phosphor-bronze wire, about 16lb. per mile.

The posts were not provided with cross arms, so the wires were run on the special brackets, which were fixed on the top of the posts as shown in Figs. 3 and 3A. The line was remarkably quiet; a slight fizzling was heard at times, but conversation could be carried on as easily as between two subscribers in one town. Both Blake and Van Rysselberghe transmitters were used.

Van Rysselberghe's system was applied to the Belgian telegraph lines during 1884, and the first line opened to the public in October. At the present moment (Nov. 1887) there are some 1,800 miles of double wire used simultaneously for telegraph (Morse and Hughes) and for telephone inter-urban trunk lines.

The author then proceeds to describe the Paris-Brussels line. It was agreed between the representatives of the two countries that the line should be a closed metallic circuit of No. 11 S.W.G. high conductivity wire, to be run on the telegraph posts on the railway, and to be protected from induction as far as possible, the means to be employed to do so being left to the respective Governments.

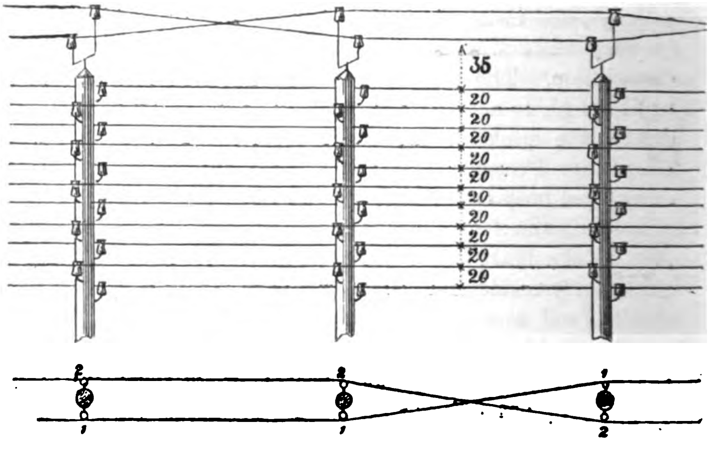

Fig. 3A.

The whole air line, 195 miles, was run in three weeks in the months of December, 1886, under great difficulties from bad weather. The length of the Belgian section is forty-eight miles. It starts from the Bourse in Brussels, and the Paris end is joined on to the Bourse there by an underground leaded cable 3 miles long.

The Belgian part of the line is run in phosphor-bronze, the French in silicium bronze. Great care had to be taken with the insulators, as good insulation was as important as freedom from induction. The system of running on the top of the poles, which had been found so satisfactory on the Brussels-Antwerp line, was adopted. But, rightly or wrongly—the author thinks the latter—the wire running department objected to the idea of the wires crossing vertically in the air, on the score of danger of wind contacts. (By a vertical cross is meant that between two poles the two wires remain respectively on the same sides of the poles, but exchange their levels, as opposed to a horizontal cross, when they retain the same respective levels, but exchange sides.)

A four-branch bracket (Fig. 4) was therefore used, so that all vertical crossings take place at the posts. The four insulators are undesirable, as every additional insulator offers an additional chance of leakage. It was found to be sufficient, however, between stations to put in a four-way bracket, and reverse vertically at every thirtieth or thirty-fifth post, and between these to reverse horizontally backwards and forwards at every sixth or seventh span, using brackets of the type already shown in Fig. 3. Fig 5 is a diagram of a portion of the line passing by the railway station at Mons, where the wires are crossed horizontally at more frequent intervals. This method does not entail cutting the wires, so that there are no more joints than in direct running.

* *Journal* Soc. Tel. Eng., Vol. VIII., 1887.

Digitized by Google

The line was first opened on February 24th, 1884, and the public can judge whether it works satisfactorily or not. As to the engineers of the two administrations, accustomed as they are to almost daily faults on a telegraph line of such a length, they are delighted with the perfect way it conducts itself. The greater part of the

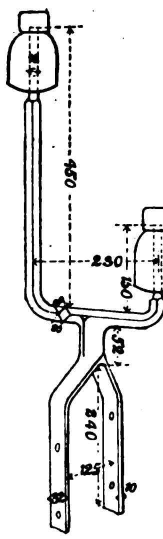

Fig. 3.

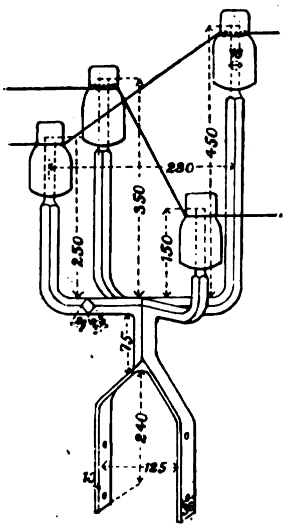

Fig. 4.

faults which have occurred have been in Brussels, where the house painters have occasionally short-circuited the overhead wires. The same wires are used simultaneously for telegraphy on the Van Rysselberghe system. The insulation and conductivity of the

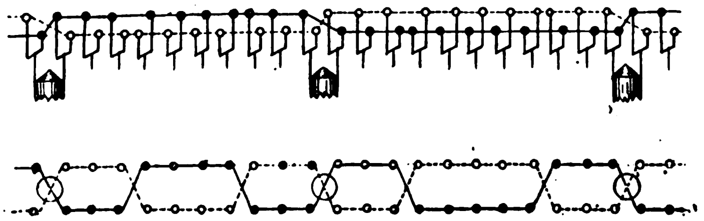

Fig. 5.

line were proved when, one winter's day, all the other telegraph wires having become unusable, the Hughes instrument got through to Paris at full speed on the telephone wires.

The two wires of the line must be alike in material and insulation. The line ceased to be silent, for example, when a Bell telephone was interposed at the frontier in one of the wires, or if one of them touched a tree branch or a damp wall.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

New York, *Feb.* 18*th*, 1888.

Some little amusement has been caused here by the prominence given in the play "L'Abbé Constantin" to Mrs. Scott and her cable. Mrs. Scott is modelled, it is said, upon Mrs. Mackay, and enlarges upon the advantages of having a cable in the family. When one owns a cable letter writing becomes not a lost but an unnecessary art, and the effect of Mrs. Scott's eloquent presentation of the delights of cable communition is to lead many of the auditors of the piece now on at Wallack's to go out and order a cable for themselves. If this exaggeration of the playwright were allowed to pass unchallenged, there is no knowing where the thing would end, and instead of a dozen Atlantic cables there would be a gross. I understand that Mr. G. G. Ward, who looks after Mr. Mackay's cable interests so ably here, has been interviewed on the subject, and has stated that after all the Bonanza King and Queen use the cable but seldom, and then pay for every message. M. Halévy notwithstanding, Mrs. Mackay is not in the habit of chatting daily with her husband 6,000 miles off, as to her latest purchases of castles, jewels, or dresses, or her options on any duchies or principalities that happen to be in the market. This little feat of talking at 6,000 miles range is, in fact, left to Mr. Stead and his special commissioner, while the Mackays, as well as the Goulds, still find use for fine stationery, crested or otherwise.

There has been quite a row in Washington over the exposure of the fact that leading firms of stockbrokers had wires running direct from the Capitol lobbies to their Wall Street offices. Mr. S. V. White, a magnate of the "Street," was sent recently to Congress, and naturally wished to have his special telegraph service as handy as possible. He therefore did only what had been done before, but someone who was jealous mentioned the matter to a newspaper correspondent, and the result of the uproar caused is that all such wires have been ordered out by Mr. Carlisle, the Speaker of the House of Representatives. Admitting, as one may, that the wires were always put to proper uses, it cannot be open to question that Congress gains in dignity by having such wires removed; for although the connection with Wall Street was openly maintained, it was impossible to avoid suspicion and even scandal. The only wires left in are those which are necessary for public and general use, and the speculating Congressman will now have to get his quotations a little less directly.

The leading event of the past week has been the meeting of the Association of Edison Companies at Chicago. This body is composed of Edison local companies and those who may be directly interested in the same, and excludes from its membership all outside supply concerns. It is also peculiar in that its sessions are held with closed doors, in this respect being more exclusive than another body equally august—the Senate of the United States—which has both public and executive sessions. The meeting at Chicago was largely attended, and its proceedings were watched with more than usual interest, from the fact that it is the first that has been held since the alternating current boom got well under headway. I have spoken with several who were present, and who participated actively in the proceedings, and I have failed to detect any evidence of nervousness or trepidation as to the future of the Edison system, or, for that matter, as to the practical superiority of the alternating over the direct current for general purposes of distribution. As the session was held with closed doors, it is somewhat difficult for me to tell what took place, but note may be made of a few interesting facts. One of these is that Mr. Edison, departing from an almost invariable rule, and overcoming an almost invincible repugnance to the effort, made an address before the association, in which he gave an exposition of his views on the subject of direct *versus* alternating currents. I understand that Mr. Edison stated frankly his unchanged conviction as to preferability of the direct current, and indicated various ways in which that current might be rendered a formidable rival to the alternating current, even on ground which has been supposed to be the peculiar province of the latter. At the same time, and in keeping with the line of thought advanced by Mr. Edison, it would not be surprising if we were to see a little increase in the E M.F. which has hitherto been observed as the standard of the Edison system; in other words, it is not unlikely, for instance, that we shall see in use a current of 330 volts instead of 220. This, as you will plainly see, is well within the safety limit, yet makes a material reduction in the quantity of copper necessary in the mains. As to the Edison municipal system, in which incandescent lamps are now run in series, and at a potential as high as 1,000 volts for street lighting and similar work, Mr. W. J. Jenks, the able manager of that department, made a very interesting report, in which considerable progress was shown, and in which the point was brought out that in not a few cases these lights had replaced and supplanted arc lights.

Mr. J. H. Vail, the general superintendent of the parent company, presented a mass of valuable statistics of various items of central station operation, &c., and brought out the astonishing fact that on the value of dynamos in Edison stations in this country the cost of repairs has been less than $1\frac{7}{10}$ths per cent. The rate would give such machines a life

Digitized by Google

of at least half a century. Mr. Vail also stated than in less than two years the number of Edison central stations had grown from 43 to 148, and the capitalisation of the stock companies from £550,000 to £2,300,000, on all of which as one investment an excellent rate of interest is being paid. The earning capacity of some of these stations was indicated by a number of load diagrams which he exhibited, one of these showing a maximum output of no less than 9,000 amperes.

I am told that one of the liveliest episodes of the convention was the reading of a paper by Mr. W. W. Mottram, who is the superintendent of the Edison Company at New Orleans. Not so many months ago Mr. Mottram's peace of mind was very much disturbed by the advent of the alternating system in the Crescent City, and he felt the ground crumbling beneath his feet, as though a Mississippi freshet were sapping his strongest dykes. Mr. Mottram, however, is a young Englishman, with the average amount of proverbial tenacity, and he made up his mind to see the thing through. At the Edison meeting, he stood up and related an extraordinary story of mishaps with the new system, and informed his brethren in the Edison faith that they had every reason to regard their position as a secure one. He had himself been obliged lately to increase the capacity of his station, and he thought that this would be the result in every case where the two systems came into direct competition. I need hardly say that Mr. Mottram's views were received with the wildest enthusiasm. Various points of interest were touched upon; the meter system of charging for current received a very strong endorsement, and the reports as to the growing use of current for electric power purposes were most encouraging. The Edison stations everywhere throughout the country are going into this business, finding that they can get so much greater return out of their plant, and that they can also render their day circuit profitable, instead of being a source of loss. There can be no question as to the present enormous rate of growth in the incandescent lighting field, and it is somewhat remarkable that American manufacturers are finding so large a market abroad. Mr. S. Bergmann brought out this point at the Edison meeting very remarkably by some figures which he gave as to his own export trade. A noteworthy little substantiation of the claims as to the growth here is given by the statement of one of the largest glass companies in the country that the demand on them at present for incandescent shades is as large as it is for gas shades.

I touched above, in speaking of the Edison Convention, on the alternating system, which is just now in this country a most engrossing theme of discussion. During the present year, as you are aware, the American Institute of Electrical Engineers in the papers of Prof. E. Thomson and Mr. W. Stanley, jun., has brought out some very valuable information on this subject, and another important contribution to the investigation was contributed at its meeting on Feb. 14, when Dr. Louis Duncan, of Johns Hopkins University, read a paper on alternating-current motors. Dr. Duncan, it will be remembered, was one of the experts who conducted the well-known Franklin Institute tests on dynamos and lamps, and he has recently been examining the subject of alternating currents, in connection with his work at the university. I have no doubt that you will publish the paper in full. He took occasion to point out that there were four forms of alternating motors which came within the bounds of possibility, though with widely different elements of practicability. The form which he seemed to regard as the most promising was that of an alternating dynamo reversed, the field being excited by continuous currents. Such a machine could be cheaply made. When once started it would govern itself perfectly, and it would give a greater output from a given source than the other machines of the alternating type. One of its disadvantages was that it must be brought into time, and that the field must be supplied with a continuous current, and that the motor would stop if a heavy load be applied suddenly. These difficulties, however, he would obviate in various ways. The paper was actively discussed, among others, by Lieut. Patten, U.S.A., who described an alternating current motor of his own design, belonging to the type first suggested by Prof. E. Thomson, in which the electro-inductive repulsion of closed coils or circuits, traversed by alternating currents, is made the principle of action. One point touched upon in the discussion was the use of the alternating motor for car traction; but it could not be said that there was a very deep impression as to the feasibility of its use in this department.

All the testimony is now in the suit of the Consolidated Stock and Petroleum Exchange against the New York Stock Exchange to prevent the latter from removing the commercial tickers from the consolidated building. The case has been on trial before one of the courts in Brooklyn. The contention of the Stock Exchange is that the quotations which are made on its floor are its own private property, the distribution or sale of which is a matter within its own discretion. The opposite contention is that that exchange is engaged in the sale and distribution of a necessity in the shape of financial news, and that it is trying to discriminate, unlawfully and unfairly, between those who desired to be its customers for this news, or is forcing the Commercial Telegraph Company, which is a public corporation, to discriminate for it. It will be interesting to see what the decision is. In the meantime the New York Stock Exchange, with the aid of the public authorities, is waging relentless warfare against the bucket shops, thirty of whose proprietors and *employés* were arrested at one swoop last Saturday. The agitation over this matter may perhaps seem trivial to some of your readers, but it is really of no small importance to the exchange, and this will be seen when I state that the business of St. Valentine's Day was only 46,000 shares. One has to go back as far as 1877 to find a parallel for this dulness, and then the total business of the lowest day was not quite so low, being 48,000 shares. The average day's work in ordinary times is 400,000 to 600,000 shares. You will not wonder, therefore, that the brokers are thirsting for the gore of the bucket-shop proprietors.

News has reached this city from the West Indies of the successful repair, after about three months' work, by the West India and Panama Cable Company's steamer "Grappler," of the cable between Jamaica and Colon. It is stated that the repairs have cost about £10,000; but it may console some of the holders of the company's stock to know that the original cable, laid seventeen years ago, was found, when picked up, to be in almost perfect condition. It seems to many here that a great deal might be done to improve the telegraph communication with the West Indies, though this is a matter which probably concerns England for the present more than it does this country. It is very certain that if the United States owned the West Indies the cable service would be a great deal better than it is.

NOTES FROM BRUSSELS.—THE LIGHTING OF THE EXHIBITION.

(FROM OUR CORRESPONDENT.)

It has already been announced that some of the principal firms in Belgium have formed themselves into a syndicate with the view of undertaking central station lighting. A technical committee of the syndicate has been appointed, whose first duty will be to consider the important question of the methods and appliances best adapted for use under the different conditions which may present themselves. The members of the committee are the following:—MM. Bonnevie (MM. Bouckaert and Co.) Gérard (Anspach, Gérard - Mignot), Goffin (Société Industrielle de Bruxelles), Julien (l'Electrique), and Van Rysselberghe (MM. Mourlon Frères). It is understood that the committee will recommend two schemes as fulfilling the requirements of municipalities proposing to undertake or to sanction the distribution of electricity—

(1.) Central station distribution by means of transformers of various systems—Gaulard-Gibbs, Zipernowsky, Goffin-Hoho, &c.

(2.) Central station distribution by means of high tension dynamos (Gérard system), charging secondary batteries at substations. Batteries of various systems may be employed, but probably those of M. Julien will have the preference. This last system is already exemplified in the successful lighting of the Théâtre de la Monnaie, installed by M. Gérard.

Digitized by Google

The Japanese are about to follow the example of their Chinese neighbours by introducing the Van Rysselberghe system of simultaneous telegraphy and telephony. It appears that this determination arose from certain successful experiments which were carried out by the students in the Physical Laboratory at Yeddo. The experiments were made on the basis of the description of the system given by MM. Charles Mourlon and Buels in their writings on telephony. The perfect success of the experiments was hailed with considerable enthusiasm by the Japanese, and a well-known Belgian firm has just received an order from the Japanese Government for a complete set of apparatus for use on one of the principal telegraph lines in Japan. We may mention in passing that the Yeddo Laboratory was fitted up throughout by Messrs. Latimer Clark, Muirhead and Co.

On the Athens-Piræus and Peloponessus Railway the Van Rysselberghe system is to be installed throughout, and will replace the present method of signalling.

We have received from our Brussels correspondent an interesting statement of the electric lighting contemplated at this year's Exhibition in Brussels ; but want of space compels us to confine our present account to the principal features thereof. It is noticeable that whereas in this country the lighting of an exhibition is now usually allotted to one or two firms who undertake the work on contract, it has in this case been determined to make the lighting an important feature of the Exhibition, and therefore it has been divided amongst a considerable number of exhibitors.

The installation has been divided into three parts :—

1. The main buildings and their annexes.
2. The fountains and façades.
3. The gardens.

The main portion of the Exhibition consists of two rectangular halls originally built for the National Exhibition of 1880. These are connected by a gallery and colonnade, in all measuring above 200 metres. The central portion contains the King's Pavilion.

The Great Hall, or gallery of machinery at the rear of the colonnade, measures 250 metres in length by 68 in width and 23 in height, and it terminates in two annexes, each 100 metres long by 60 broad.

This main gallery or hall is to be lit by 84 arc lamps chosen from the systems of Piette and Krizig, Dulait, Thomson-Houston, De Puyt and Pitot.

The lamps will be suspended at heights varying from 7 to 10 metres, and from 10 to 16 metres apart.

The Salle des Fêtes, 3,000 square metres in extent, is the object of special enterprise, for which many electrical firms have submitted plans and tenders. The arc lamps to be supplied will probably number 10 or 12, with incandescent lamps of the Victoria or Swan and Edison pattern between the pillars.

In the Hall d'Honneur there will be 8 lamps of high power.

The *loges* will be lit by Bernstein lamps of 3 to 5 candle-power. MM. Bouckaert and Co. furnish 4 lights of 320 candle-power on the outer garden slopes, which will illuminate the salient features of the building. At the end of the gardens there will be two Dulait lights, 25 metres high, equal to 10,000 candles, marking the entrance of the Exhibition. The illumination is to be carried all along the Rue de la Loi. The right annexe of the Central Hall is to be served by 38 arc lamps, of from 35 to 90 candle-power, selected from the systems of De Puyt, Dulait and Piette and Krizig, and the left annexe by 30 lamps supplied by Ganz and Co. This is equivalent to one lamp per 80 square metres superficial, with 5 metres in height, or 28 candle metres intensity, which is a trifle above the average of the lighting in the machinery gallery. Eight Thomson-Houstons, placed 18 metres high, each 2,000 candle-power, will light the outer gardens of the annexes. These lights will absorb in all about 350 horse-power, leaving 150 horse-power for the lighting of the pavilion, façades, &c.

The illumination of the fountains will be entrusted either to Mr. Galloway or Messrs. Sennett and Pieper, and ultimately the lighting of the gardens and pathways will be included. Water-power will likewise be furnished to the extent of 150 horse-power for a machine in one of the courts of the Aquarium.

The Aquarium, the Kursaal, and the Great Brewery are to be lit by Pieper, of Liége. In the English section the work will be done by the old plant brought from Manchester.* No fewer than 25,000 gas jets, in festoons, are to be distributed in and about the alleys and groves of the gardens. Gérard and Co., who were among the earliest to demonstrate the practicability of the electric light for public purposes, will probably be called upon to light the Rue de la Loi.

Taken altogether we are led to expect a very substantial and effective installation in connection with the approaching Exhibition.

* We were under the impression that this plant had been sent to Glasgow.—Ed. *E.*

CORRESPONDENCE.

THE NOTATION OF MAGNETIC QUANTITIES.

[*Translation.*]

TO THE EDITOR OF THE ELECTRICIAN.

Sir : In the issue of your esteemed journal for the 24th February, Mr. James Swinburne takes me to task for a fault of which I am perfectly innocent. I appeal to the shade of Maxwell, according to whom we have hitherto imagined electrostatic resistance considered according to the theory of dimensions to be of the nature of a *slowness*—that is, the inverse of a velocity. In designating by $\mathfrak{J}$ the magneto-motive force, ϕ the flux of force, and $\mathfrak{R}$ the magnetic resistance, I had not any intention of touching upon quaternian methods ; my object was more simple and more practical. All the capital and italic letters ordinarily employed being already required to designate physical quantities other than magnetic quantities, I have simply used Greek and *lettres de ronde*—not German letters—to note the flux of force, magnetic motive force, and magnetic resistance. The vectors, scalars, and quaternions have nothing to do with these ordinary algebraic notations. But where Mr. Swinburne is archi-hypercritical is when he confounds the magnetic resistance with its inverse, the magnetic conductibility, and attributes to me an error which belongs properly to himself. I read in effect (page 412) "and R denotes the magnetic resistance which appears to be μ multiplied by the area and divided by the length of the magnetic circuit."

This definition, which Mr. Swinburne attributes to me, is that of the inverse of the magnetic resistance, a definition which latter may also be found—this time correctly given—in the same number (page 408) in an article by Prof. Geo. Forbes on "Formulæ for Converters." In this paper the magnetic resistance is defined thus

$$\rho = \frac{\text{mean length of lines of induction in the iron}}{\text{cross-sectional area of iron} \times \text{permeability}}.$$

I have designated by $\mathfrak{R}$ the same thing which Prof. Forbes calls "ρ," and Mr. Gisbert Kapp calls R, and it is difficult to understand where the difficulty lies in accepting one or other of these notations. As to an international notation, I recognise with profound regret that we are as far from it as ever.
—Yours, &c., E. Hospitalier.

STARTING THE DYNAMO ON TO THE ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir : Perhaps others, as well as myself, have experienced some little difficulty in putting the charging dynamo on to the accumulator battery exactly at the right time—*i.e.*, just when the E.M.F. of the machine is equal to the E.M.F. of the battery—and I have often seen heavy sparking at the commutators and the armatures, probably strained by the connection being made too early or too late.

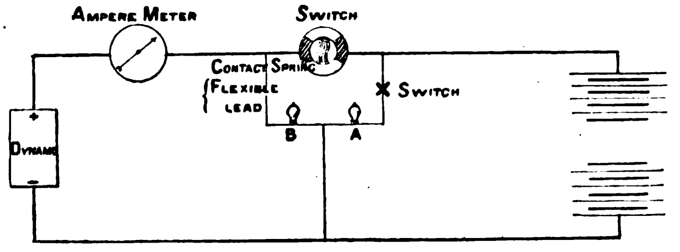

Fig. 1.

Some of the automatic appliances made for this purpose get over the difficulty to some extent, as they are generally set to make the contact when the volts on both sides are approximately equal ; but such apparatus are costly at least.

I found using a voltmeter also not so convenient as the very simple plan shown diagramatically in the accompanying sketch (Fig. 1).

Digitized by Google

The lamps A and B are first selected as giving the same light with the same E.M.F. The lamp A, it will be seen, is lighted from the accumulators, and B is connected with the machine. If now the machine is started B will gradually become bright as the speed increases, and by watching until the light given by the two lamps is equal, and then closing the switch D, the circuit is made without the least sparking at the commutator, and without throwing any strain whatever on the armature of the dynamo; for if a double-ended current indicator be placed in the circuit it will be seen that it remains at O, with scarcely a tremor, even when closing the switch.

Here we have several dynamos which have to be coupled parallel on to the battery (the number of cells in which also varies greatly) one after another; this makes it still more difficult to use automatic apparatus. In our case the connection from lamp B is a flexible wire to attach to any dynamo switch with a spring as required.

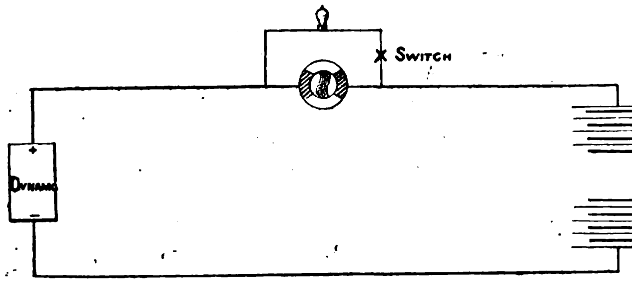

Fig. 2.

A modification of the above, which also answers fairly well, is shown in sketch (Fig. 2). In this case the P circuit is complete through the lamp, then as the E.M.F. of the dynamo rises it will oppose the E.M.F. of the battery, and the main switch is closed just as the lamp ceases to glow. In this case it is advisable to make the main switch also switch *out* the lamp when the battery is put in, in such a manner that the lamp can only be lighted again by a movement independent of the main switch.—Yours, &c., T. W. W. Melhuish.

Vienna, Feb. 25th, 1888.

ELECTRIC TRACTION: CLOSED CONDUIT SYSTEMS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Mr. W. Geipel, p. 357 of the present volume, says:—"A plan has also been proposed by them (Profs. Ayrton and Perry) for employing the attraction of a magnet fixed on the car and keepers fixed in boxes underneath the street. The contacts on the keepers are permanently connected with the underground conductor, and when lifted by the attractive force of the magnet on the car they make connection with a section of rail putting the motor in circuit."

This is just about the description of my own and Mr. Binswanger's system, invented, designed, and patented in November, 1886.

As I know Profs. Ayrton and Perry before this date had not proposed tramways on the parallel system described, if Mr. Geipel would examine a copy of their patent of 1883, No. 2,395, p. 14, he would see at once what was their opinion of the parallel system at that date and what has been done.

But as I may not know all of the numerous works of Profs. Ayrton and Perry, Mr. W. Geipel would oblige me very much by pointing out the dates and papers in connection with the system mentioned by him.—Yours, &c., Charles Pollak.

11, Rue Descartes, Paris, Feb. 26, 1888.

THE STABILITY OF TELEGRAPH WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The education of Mr. Frank Caws as a telegraph-engineer is proceeding apace; but he has yet to learn a great deal before he thoroughly realises the conditions that determine the stability of a telegraph line. His experiments are mere repetitions of those which most responsible engineers performed for themselves more than a quarter of a century ago, but without his errors. In conducting them he has committed several fallacies, but the most serious one is that from erroneous data he has calculated a certain curve which he has caused his apparatus to reproduce, and this he calls his experimental curve.

If Mr. Caws' figures show anything at all they show that our wires have a greater factor of safety than I have allowed; but his data are wrong, his curves are wrong, and he is working in the dark. A telegraph wire is freely suspended between two rigidly fixed points. We have to regard what takes place in only one span. Omitting external stresses, the changes of form in this span are changes due to variations of temperature. The changes of strain are changes due to its own elasticity. We do not care for variations of form or of strain due to internal stresses provided we are well within the margin of safety, and all the wires in one span are affected equally and similarly. What we have to guard against are external stresses, due to wind, snow, ice, falling trees, poles and signal posts, &c., stresses often exceeding the limits of elasticity. Mr. Caws should do what engineers have done, viz., permanently fix up a span of wire and watch and record its vagaries for three or more years; he should also experiment with stresses producing the breaking strain of the wire. He will then acquire a little light on the stability of a telegraph line, and learn why the tendency is to shorten spans, to increase the tensile strength of wires, and to smile at springs.—Yours, &c., W. H. Preece.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I noticed in last week's edition of your journal that Mr. Caws, in Part II. of his article, "Experiments on the Conditions which Determine the Stability of a Telegraph Wire," gives a diagram showing how the experiments were performed. From this Mr. Caws has apparently quite forgotten the weight of the Salter's spring-balance and the linesman's vice upon the line-wire. Mr. Caws states he adjusts the nuts "so that the angles of the line-wire may be equal on both sides of the pulley, which is evidenced by the thermometer-plummet." In that case he intends to make a balance upon his plated pulley of the span of line-wire upon one side and the linesman's vice and spring-balance upon the other, without allowing anything in the dip for so doing. I think Mr. Caws has made a great mistake, and applied an impractical method, the result of which cannot be the true table of dips and stresses.—Yours, &c., Robt. S. Bozon.

INDUCTANCE AND RESISTANCE IN TELEPHONE CIRCUITS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of 3rd February you draw attention to an article in the *Phil. Mag.*, by Mr. Oliver Heaviside, in which he makes what appears to me to be a remarkable statement. I hope I shall not occupy too much of your valuable space by quoting it *in extenso* as follows:—"It seems to be imagined that self-induction is harmful to long-distance telephony. The precise contrary is the case. It is the very life and soul of it, as is proved both by practical experience in America and on the Continent on very long copper circuits, and by examining the theory of the matter. I have proved this in considerable detail; but they will not believe it. . . . It is resistance that is so harmful, not self-induction."

This appears to be so entirely contradicted by other authorities on the subject and by experiment, that I feel sure all telephonists must—like myself—wish that Mr. Heaviside would give us an explanation of his reasons which can be understood by us as well as by the talented few who can fully appreciate his article.

Prof. S. Thompson, during a discussion on this subject at the Society of Telegraph-Engineers, May, 1886, said: "The best thing to do is to keep up the resistance by using thin conductors such as silica-bronze or phosphor-bronze, at the same time keeping down self-induction by avoiding unnecessary turns in the coils and unnecessarily large iron cores." An American authority, speaking of copper wire conductors, also states that "no advantage can be distinguished in the use of

Digitized by Google

No. 12 gauge over that of No. 18 in working the metallic circuits between Philadelphia and New York."

From actual experiments on all kinds of telephone circuits, I have invariably found that when a high resistance with little or no inductance was inserted it had scarcely any effect in weakening the received sound, but that there was a considerable diminution when a coil of comparatively low resistance but of large inductance was substituted for the high resistance.

This would appear to point to high resistance in the circuit being unimportant, and that the great point is to reduce the inductance, and I hope, therefore, that Mr. Heaviside will see his way to explain where is the fallacy of such deductions. —Yours, &c., F. B. HAWES.

THE PROPOSED LIGHTING OF THE CITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the notice in your issue of last Friday anent the proposal of the Anglo-American Brush Company to light a certain area of the City of London, will you kindly allow me to express the feelings of regret with which I learned the Commissioners of Sewers had again rejected the proposal, owing apparently to the ungallant interference at the eleventh hour on the part of the Maxim-Weston Company?

For some time past I, as one deeply interested in the introduction of the electric light to Dublin, have been watching with no little anxiety the progress of this proposal, believing that its final acceptance would be the means of imparting a considerable impetus to the electrical industry.

It is much to be regretted that those praiseworthy negotiations (now extending, I believe, over some years) to undertake an interesting and highly important work on a legitimate and properly considered commercial basis, should be as it were invaded by the overtures of a practically untried company, whose electrical apparatus has not, as yet, come very conspicuously before the public.

It would have been very much more conducive to the interests of the electric light generally if Mr. Watt's company had gracefully stood aside and allowed the work in question to be carried out without obstruction by those who had spent so much time and energy in working the matter up to its present position.

I believe that until some such general scheme as that proposed is in practical operation in London, we in the provinces shall have to wait a long time before our desire to see the new illuminant installed in our streets and houses is gratified.

Therefore it is that I earnestly hope the City Commissioners will reconsider their decision of Tuesday last, and find it to their advantage to come to terms without delay for a grand scheme of electric lighting on a sound commercial basis.—Yours, &c., ANGELO FAHIE, M.S.T.E. & E.

SHALLENBERGER'S SYSTEM OF STREET LIGHTING BY ALTERNATING CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of January 13th, 1888, you refer to Mr. Stanley's mention of M. Shallenberger's system of street lighting. Some months ago while doing some work upon an electrical instrument, in which I was using a self-induction coil in series with a dead resistance, I noticed the same apparent increase of E.M.F. mentioned by Mr. Stanley.

After making several tests to find the cause of this increase, I arrived at the following explanation, which I believe correct:—

I can best state the solution that I arrived at by assuming a special case and endeavouring to explain it. Let us suppose that we have a series of four 50-volt lamps across a 200-volt circuit, as in Mr. Stanley's example. Each lamp is shunted by a self-induction coil. Suppose that the E.M.F.'s are all to be measured by a Cardew voltmeter.

The current taken by a Cardew voltmeter increases nearly as the E.M.F. which it measures. The heating effect upon its wire, it must be remembered, increases as the square of this current. When all the lamps and coils are in place the voltmeter will indicate 200 volts as the total E.M.F., and 50 volts as the portion of this total acting upon each lamp.

The self-induction of the four coils is so high that practically no current is taken by them; but let one of the lamps be removed and the conditions are changed. We will consider the effect of this change during one wave phase.

First, let the E.M.F. of our alternating current be passing from zero to some definite value. The self-induction coil from which the lamp has been removed will now receive more than its share of the E.M.F. of the circuit, being in series with coils that are shunted by lamps. But the coils are so constructed (as to amount of iron and length of wire) that the increased E.M.F. to which the unshunted coil is exposed soon overcomes its power of self-induction [? the iron core is magnetised to saturation.—ED. *E.*], this taking place before the wave of E.M.F. is completed. The iron of the coil having once exerted the full inductive effect of which it is capable permits the remainder of the current produced by the E.M.F. impulse under consideration to pass the coil practically at a short circuit. The ohmic or dead resistance of the wire of the coil may be made very small, as compared with the resistance of the lamps, and will be disregarded at present.

To express the above idea in fewer words, I would say that the increase of E.M.F. upon one coil that occurs when it is placed in series with three shunted coils overcomes the self-induction of the single coil before the reversal of the current has taken place. After the self-induction of the coil is overcome the total potential of the circuit is divided between three lamps and a low-resistance wire—the wire of the unshunted coil. If the coil has been properly constructed about one-quarter of the energy of the E.M.F. wave was spent in overcoming its self-induction, and we will assume that this energy was expended upon the coil in one-third of the time of the wave phase.

During the remaining time of the wave there will be sufficient current pass in the circuit (owing to the self-induction factor having disappeared in the resistance of the unshunted coil, and to the heating effect of the current upon the lamps increasing as the current squared) to keep the remaining lamps at full candle-power.

It is evident that a Cardew voltmeter measuring the E.M.F. at the terminals of the working self-induction coil would have received during a portion (assumed to be one-third) of the time of the E.M.F. wave three or perhaps nearly four times as much current as it would have received during the same time if the potential of the circuit had been evenly distributed between the four-lamp resistances, because the counter E.M.F. of the coil offered a high or nearly infinite resistance to the passage of the current until its effect was overcome. This increase of current in the voltmeter to about three times its normal amount for one-third of the time of a wave phase gives a heating effect upon the wire of the voltmeter nine times as great as it would have been if the potential had been evenly distributed. But to get a reading of fifty volts we should have only three times as much heat, or $\sqrt{3}$ times as much current for one-third of the time of the E.M.F. wave as with the even distribution of potential.

The generation of heat during one-third of the time of each E.M.F. wave, nine times as fast as is required to give a deflection of 50 volts on the voltmeter, produces three times as much heat in the voltmeter wire as gives a reading of 50 volts, or about as much heat as would be required to give a reading of $\sqrt{3} \times 50$ volts.

During the fall of potential from a positive or negative value to zero there is no difference of potential required to keep up the current in the working self-induction coil (disregarding the dead resistance of the wire of the coil). There is not only no counter self-induction during the fall, but the coil may even add slightly to the E.M.F. of the circuit. The same cause that produces an after current giving rise to a discharge spark when a circuit exciting a large electro-magnet is broken, produces in the case of a self-induction coil an after current, tending to keep up the E.M.F. of the circuit when the potential is changing from a positive or negative value to zero. This discharge current, if its effect is sufficient to be

Digitized by Google

noticed, will unite with the other causes in making the voltmeter read too high.

For the above reasons it would occur that in measuring the E.M.F. at the terminals of the coil from which the lamp has been removed with a Cardew voltmeter a false reading is obtained, while a voltmeter measuring the potential at the lamps will read 50 volts for each lamp if the 50-volt lamps are at candle-power. The reading of the voltmeter must be 50 volts when the lamps are at candle-power, since the light given from the lamp and the reading of the Cardew instrument both depend upon the heating of a conductor, carbon, or wire.

I have disregarded the effect of the current taken by the voltmeter upon the distribution of the potential, and also the effect due to the leakage of the three shunt coils. The leakage of the three coils shunting the lamps is very slight, as they are not subjected to sufficient E.M.F. for a long enough time to overcome their self-induction. In this connection I have made several series of measurements, showing that the leakage current in a self-induction coil increases very rapidly, as the E.M.F. upon the coil increases, if the coil is working near the point of magnetic saturation of the iron.

The argument that I have presented must be somewhat modified in practice on account of the rise and fall of potential being gradual, and not abrupt. This consideration is especially involved when it is assumed that one-third of the time of the wave phase is consumed in overcoming the self-induction of the unshunted coil, one-third being only an approximate value for the special conditions considered. I hope, however, that what I have said will serve to express the idea aimed at. A series of twenty 50-volt lamps can be so arranged with shunt coils that one broken lamp will not only be replaced by its coil, but the total resistance of the series to the alternating current will be so modified when one lamp breaks that the remaining nineteen lamps will burn more brightly than before the twentieth lamp broke.

In practice, in the Westinghouse Electric Company's street lighting system three or four out of a series of twenty lamps arranged with shunt self-induction coils can be removed before the remainder become perceptibly dimmer; yet there is reason to believe that the total energy consumed in the circuit is reduced each time a lamp is taken out of the series.—Yours, &c., FREDK. DARLINGTON.

Allegheny City, Penn.

[We believe our correspondent's explanation to be the correct one.—ED. *E.*]

THE DEPOSITION OF ALUMINIUM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of February 3rd, you refer to the deposition of aluminium electrolytically and give a receipt as set forth by Mr. Herman Reinbold. I should be very much obliged if you could give me any reference as to where I could get fuller particulars. I tried the receipt and entirely failed in getting any aluminium deposited, whatever the strength of current was.—Yours, &c., R. H. C. NEVILE.

Wellingore Hall, Grantham, Feb. 18, 1888.

[Perhaps some of our readers can give our correspondent the benefit of their experience.—ED. *E.*]

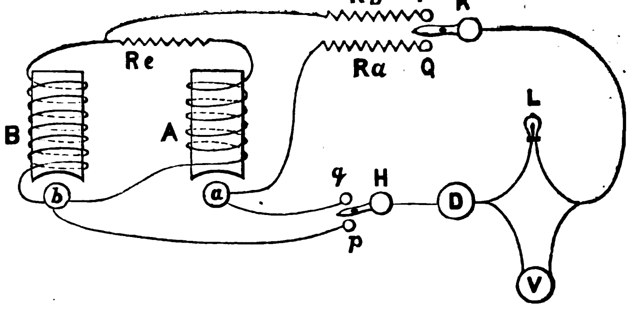
PHYSICAL SOCIETY.

At the meeting of this society on Saturday, Feb. 25, Prof. Ayrton communicated a note by himself and Prof. Perry,

"ON THE EFFICIENCY OF INCANDESCENT LAMPS WITH DIRECT AND ALTERNATE CURRENTS."

Prof. AYRTON stated that the object of the experiments described in the present communication was to determine whether, for a given amount of power supplied to an incandescent lamp, a larger amount of light would be obtained by using direct or alternate currents respectively; in other words, which of these systems, direct or alternate currents, would be the more advantageous to the householder paying a stipulated amount for each Board of Trade unit? To solve this question a large number of experiments was made, in which the light of a lamp supplied with direct and alternate currents respectively was compared with the light of a standard candle.

The arrangement employed is shown below:—



A Alternate current (Ferranti) dynamo; *a* its armature.
B Direct current (Gramme) dynamo; *b* its armature.
D Dynamometer. V Voltmeter. L Indandescent Lamp. H and K Switches. P*p* and Q*q* Terminals. R*a*, R*b*, R*e*, Adjustable resistances regulating alternating and direct current dynamo circuits and Ferranti exciting circuit respectively.

The Gramme machine was used, as indicated in the diagram, to excite the Ferranti alternate-current dynamo. By means of the switches K and H the lamp circuit could be connected with the Gramme machine through the terminals P and *p*, the Ferranti being at the same time thrown out of the circuit; and it also could be connected with the Ferranti machine through the terminals Q and *q*. The current supplied to the lamp was regulated by means of the adjustable resistances R_a and R_b, and the exciting current of the Ferranti machine was regulated by the adjustable resistance R_e. The reflecting dynamometer used was constructed with very fine wire to eliminate the error which would otherwise arise from want of uniformity in the distribution of current in the wire, and it was sufficiently delicate to have measured a much smaller current than was actually used. It was therefore necessary to use a large controlling face in order to keep the spot of light upon the screen. The potential difference between the lamp terminals was measured by a voltmeter of the improved Cardew type, recently devised by the authors. The actual measured value of the watts supplied would be given for the alternate currents by the product of the readings of the dynamometer and the voltmeter, namely, the product of the square root of the mean square of amperes into the square root of the mean square of volts. The result so obtained is, however, higher than the true value on account of the effect of self-induction in the dynamometer.

The true value had to be calculated from the formula—

$$\frac{\text{number of true watts}}{\text{number of measured watts}} = \frac{r\,\tau}{\sqrt{L^2\,\pi^2 + r^2\,\tau^2}},$$

or,

$$\text{true value of watts} = \frac{r\,\tau\sqrt{\overline{V}^2 . \overline{A}^2}}{\sqrt{L^2\,\pi^2 + r^2\,\tau^2}},$$

where $\overline{V}$ is the mean value of the potential in volts, $\overline{A}$ that of the current in amperes, r is the resistance of the dynamometer, and L its coefficient of self-induction, and τ is the period of alternation. The photometer used was a divided paraffin disc photometer, the disc consisting of two half discs of paraffin separated by silver foil. In order to eliminate a possible error arising from irregularity in the standard candle the observations were made in series with the two machines alternately. In the first experiments an Edison-Swan lamp was used. These observations, however, had to be rejected, as it was found that an error had been introduced by the induction of a metallic box containing the damper of the dynamometer. In the subsequent experiments this was replaced by a wooden box, and as it was feared that the filament, which in this lamp is in the form of a loop, might have a sensible amount of self-induction, Maxim-Weston lamps, having an M-shaped filament, or lamps with an ordinary horseshoe filament, were used. Observations were made with red and green as well as with white light, by the use of ruby-red and signal-green glass, and the speed of alternation was varied from 1-150th to 1-480th of a second. The result of the experiments was that no difference could be detected between the amount of light obtained from the direct and alternating currents respectively, provided the power, properly measured, was the same in each case.

The result of 75 observations gave 3·3989 for direct currents, and 3·3955 for alternate currents, as the amount of light obtained from the lamp in terms of the standard candle for a power of one watt.

The Professor remarked that very probably the life of a lamp

Digitized by Google

might be shorter with alternate currents, but there are at present no reliable data to determine the question. He stated that he had seen tables professing to give such data, but they appeared to be mere arithmetic not founded upon experiment, and in one case the results given virtually implied that experiments had been made by the author of the table not merely before incandescent lamps had been invented, but before the supposed observer was born. Prof. Ayrton also mentioned that it had been stated that the use of an accumulator makes the life of a lamp longer than when supplied direct from the dynamo, even if a direct-current machine were used, but he was not aware that there were sufficient data available to warrant the conclusion.

In a paper read before the society in February, 1885 (*Phil. Mag.*, April, 1885), the authors found that the amount of light given by a lamp supplied by a direct current is given approximately by a formula of the form

$$l = a\,(V - b)^3,$$

where l is the amount of light, V the potential difference between the lamp terminals, and a and b are constants, b being the lowest value of V at which the filament begins to be luminous. This is for white light; for green light they find that

$$l = a\,(V - b)^{4 \cdot 44}.$$

In red light, on the other hand, the index is less than 3, but they have not yet succeeded in getting a satisfactory determination.

The authors calculated the amount of light which would be given by a lamp supplied by alternate currents, on the assumption that the proper value to be given to V was its mean value, and the square root of its mean square respectively; but in neither case were results obtained in agreement with the formula found to hold in the case of direct currents.

Mr. SWINBURNE stated that he had found a difference in the light obtained in the case of direct and alternate currents. He did not think the self-induction of the loop of an Edison-Swan lamp would be of sensible amount with currents much below 400 to 500 amperes. He did not find that the current density in the filament had any effect on the resistance of the lamp, but that it only altered the temperature of the filament. He suggested that no allowance had been made for the capacity for heat of the filament known experimentally to exist. He thought that the life of lamps would be greatly increased when better governors were available.

Prof. S. P. THOMPSON remarked that while the experiments showed that the total power was the same for given brightness, it would be of interest to know if both the factors of the work remained the same, namely, whether the average resistance of the lamp was the same in each case. The central portion of the filament would appear to be hotter than the external portion, so that there would be a different current density at the centre, and this would doubtless vary in the case of direct and alternate currents. It would not necessarily follow that there would be a similar difference for the outside portion, so that the light might be the same in each case.

He stated that he had noticed a periodic variation in the light from alternate currents, and when at an hotel had often moved a mirror backwards and forwards in front of a lamp which would show this variation if it existed, and therefore give a means of knowing whether the machine in use was an alternate or direct-current dynamo. This period, however, was much longer than the period of alternation, and he had on a previous occasion pointed out that any want of symmetry in the field-magnets of the dynamo would give rise to a periodic variation in the E.M.F., the period being equal to that of rotation. He thought that attention ought to be given to the improvement of photometers, and in the instrument used he pointed out that when the disc was moved from or towards either source of light the rays from that source would fall on it at a different angle, so that if the illumination were balanced at the centre it would not be so at the edges.

He had found great difficulty with standard candles, as he had found that the brightness depended on the length of the wick, and that when the candle was snuffed the brightness was increased by a considerable percentage.

Supposing the light varied periodically, we should then have to consider how the eye integrated the impressions received. Fechner's law might in general be held to give approximate results, but we did not know how far it would apply to rapid changes; fortunately however, the specific heat of the carbon filament prevents any serious alteration in brightness.

Mr. BOYS stated that Prof. Guthrie had made photometric experiments which showed that the eye did integrate properly the impressions which it received.

Prof. PERRY stated he and Prof. Ayrton had made remarks to the same effect as those of Prof. Thompson on the physiological aspect of the question when Prof. Guthrie's experiments were described, and in answer to a question asked (by Prof. Perry) at the Royal Society on that occasion Captain Abney stated that he had found that Prof. Guthrie's photometer gave perfectly accurate results.

Prof. AYRTON said that he understood Mr. Swinburne to say that he got different dynamometer indications for the same amount of light in the case of direct and alternate currents respectively, and suggested that this was probably due to errors in the dynamometer. The dynamometer used by them was especially constructed to ensure extreme accuracy, and waste of power was of no importance, but ordinary dynamometers for commercial purposes were usually constructed of thick wire, so as to waste as little power as possible. He stated that when he had been at Chatham Captain Cardew had told him of such a difference in the dynamometer indications, but their experiments carried out with special precautions and a specially constructed dynamometer showed that the amount of light was the same for a given expenditure of power with either alternate or direct currents.

He quite agreed with Prof. Thompson's objections to the photometers in use and to dependence on standard candles, but these would not have any effect on the present experiments, owing to the plan adopted of making a rapid succession of alternate observations with the two dynamos.

Prof. PERRY, in reply to Prof. Thompson's remarks on the slope of temperature from the inside to the outside of the filament, stated that, in 1874, owing to a letter in *Nature* calling in question Dr. Macfarlane's results on the radiation of copper spheres, on the ground that he had not taken account of the internal conductivity, he had made a series of experiments carried out with great care, and had found that it had no appreciable effect on the radiation, and he believed the same would hold good for the lamp filament. Prof. Ayrton considered that the conclusions usually drawn from Balfour Stewart's radiation experiments are erroneous, and that really white bodies emit more light, when heated, than black ones, so that it would be advantageous to use some white substance for the filament itself, or to coat the filament with such a substance. He mentioned that Mr. Bottomley had shown experimentally that a bright platinum wire gives more light than a blackened one.

Prof. AYRTON stated that he was endeavouring to carry out this idea.

SWITCH-BOARDS.

We illustrate herewith some switching apparatus designed by Drake and Gorham, and made by the United Electrical Engineer-

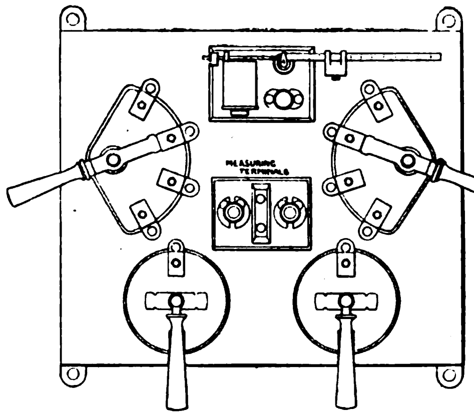


FIG. 1.

ing Company, and which have been approved by use on various important installations. The standard types are specially adapted for use with accumulators, but varieties are supplied combining all the accessories required in particular cases. Fig. 1 shows the arrangement. It includes two regulator switches, "charging" and "discharging," the dynamo being joined up to the "charging" switch, and the line circuit to the "discharging" switch. The last four accumulator cells are joined up respectively to the contacts of both switches, the obvious advantage of this arrangement being that the dynamo and lamps can be joined up independently to any of the last accumulator cells and any desired combination can be thus effected. There is also an "on" and "off" switch for both dynamo and lamp circuit, and a plug-measuring block by which the dynamo current or the current going to line can be measured.

Fig. 2 is a section showing connecting socket, into which the necessary connections are sweated at the backs of the switch-boards, thus ensuring the utmost possible safety and complying with insurance requirements.

The latest form of regulating switch is shown in Fig. 3. While charging and discharging it is frequently necessary to vary the number of cells in circuit; these switches effect this without short-circuiting or perceptibly interrupting the current. The special form

Digitized by Google

of the ring ensures thoroughly good contact, and the adjusting arrangement preserves their efficiency for practically any length of time.

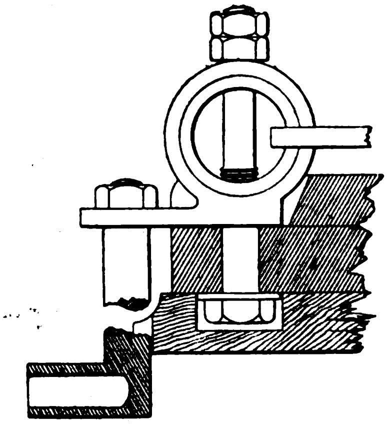

Fig. 2.

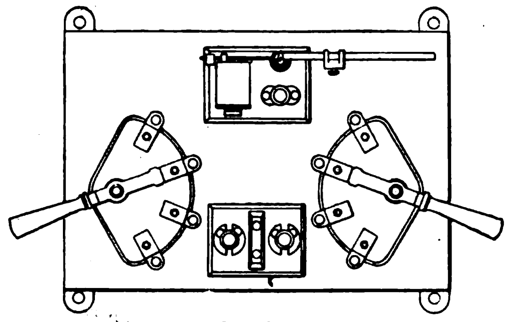

Fig. 3.

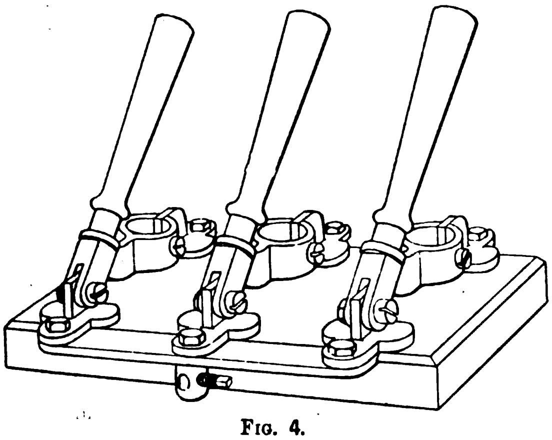

Fig. 4.

Fig. 4 illustrates a new application of the adjustable ring contacts to branch-line switches, which are used on the switch-boards to control the various circuits.

PHOTOMETRY.—THE PENTANE STANDARD LAMP NO. 2.

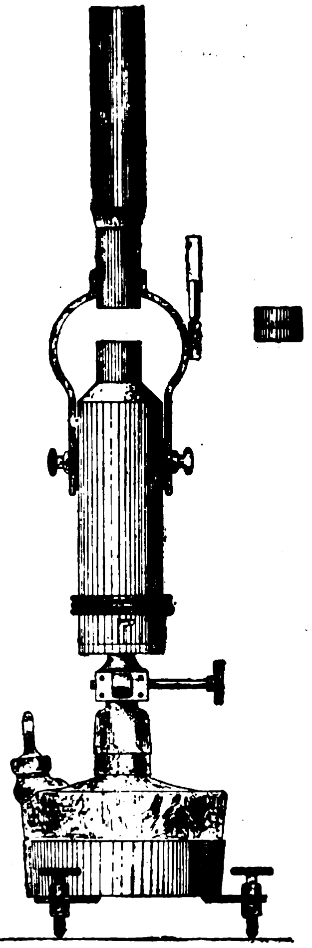
We have recently had occasion to draw attention to the pentane standard lamp devised by Mr. A. Vernon Harcourt and made by the Woodhouse and Rawson Electric Manufacturing Company.

The excellent work done by this lamp has been shown by Mr. W. T. Dibden in his Report upon Standards of Light to the Metropolitan Board of Works, in which the lamp stood at the head of all the standards tested, and yielded the exceedingly good average of 97 per cent. of tests within 1 per cent. the mean value, a result we take it never before reached by any standard tested under similar conditions.

We understand that Mr. Harcourt's aim in devising this lamp was to produce a portable and self-contained instrument, dispensing with some of the more bulky apparatus employed in his well-known pentane standard.

Notwithstanding the excellent results attained by this lamp, Mr. Harcourt believed he could construct a lamp on a somewhat different principle which would be equally exact and more easily managed. This new form of lamp he exhibited before the Physical Section of the British Association at its meeting in Manchester this year. The new lamp has been put into the hands of the makers of the former lamp, and we append a sketch of it. The new form of lamp instead of burning a mixture of air and pentane burns pentane vapour only, and though unprovided with any glass chimney round the flame burns steadily, even when exposed to moderate draughts. At the same time, the important condition that the colour of the flame produced by the direct combustion of the rich pentane vapour should be as white as possible is accomplished, as will be shown by the same apparatus.

It will be seen from our sketch that the lamp takes a form some what similar to an ordinary spirit lamp with an additional metal chimney above. The metal chimney, by producing a strong upward draught, serves a two-fold purpose ; (1) the flame is kept



exceedingly steady, and (2) the temperature of combustion is raised and a whiter light is produced.

It will also be seen that a wick is employed, which would be a distinct disadvantage were it used, as wicks generally are, within the flame or close to the point of combustion of the vapour ; but in this case the wick remains at a distance of two or three inches from the point of ignition, and serves only to convey the liquid pentane by capillary action to a part of the tube in which it is volatilised by the warmth conducted downwards from the flame. The wick, it will be observed, is enclosed in a tube, in which it fits comfortably, and which is open at the upper and lower ends. This tube is jacketed by a larger tube, to which it is attached by flat plates. This jacketing serves to produce a steady temperature of the liquid and vapour contained within it, the vapour burning as it is produced at the upper extremity of the tube. These two tubes are further jacketed by another larger one, the upper portion of which is contracted into a smaller tube, which is of the same size as the lower portion of the chimney.

The chimney itself is enlarged in its upper portion, and is attached by two metal bands to the exterior of the larger part of the lower tube. The bands are so shaped as to be at some distance from the flame, and, by means of slots cut in their lower portion, the chimney of the lamp can be moved up and down within the necessary limits. The lower tube is removable, and is attached to a gallery (solidly fastened to the base of the lamp) by a bayonet joint.

The action of the lamp is as follows :—On removing the lower tube and warming the inner tubes the pentane vapour rises from the opening in the small tube and can there be lighted. On putting on again the large tube with the chimney attached the flame rises

Digitized by Google

above the top of the edge of the lower tube, and by slightly raising the wick the top of it passes into the chimney. In this chimney two narrow slots of 10mm. high are cut diametrically opposite to each other, so that the tip of the flame may be seen through either of them. When the movable chimney is set at a definite height above the upper edge of the lower tube, and the flame is raised so that its tip is seen to be somewhere between the upper and lower limits of the slots, the central portion of the flame appearing between the upper edge of the lower tube and the lower edge of the chimney gives a definite quantity of light.

It is well known that the light emitted from the centre of a flame is little affected by considerable variations in the height of the flame. With the flame of this lamp Mr. Harcourt has found experimentally what part is of the most constant brightness and what variation in the height of the flame may be made without affecting measurably the brightness of this part. The actual position of the interval between the lower tube and the chimney, and the length of the slot opposite to any part of which the tip of the flame may be, are the outcome of these experiments. Mr. Harcourt has found, and his results have been confirmed by subsequent experiments at the makers' factory, what portions of the flame must be selected to give a light of one candle or 1½ or half-candle, as may be preferred.

Of course any intermediate values can also be obtained by setting the chimney at various heights above the lower tube, and thus altering the amount of light visible between the upper and lower tubes.

The method for accurately setting the height of the chimney is both ingenious and simple; in fact, it forms one of the most attractive features of the lamp. Small gauges of accurate height, and exactly fitting the outside diameter of the upper and lower tubes, are inserted between them; the chimney is lowered until it rests firmly and securely upon the gauge; it is then screwed tightly to the lower cylinder by means of set screws, and the gauge is withdrawn horizontally, leaving, of course, a distance between the two tubes exactly equal to its height. In the case of the gauge requisite to obtain half a candle it is found necessary to add a small collar upon the lower tube, so as to ensure a portion of the flame being used which will remain perfectly constant, even though the height of the flame vary within the prescribed limits. This variation of the height of the flame is found to be exceedingly small after the lamp has been alight for ten minutes or a quarter of an hour and the inner tube has reached a constant temperature, the constancy of which temperature is greatly increased by the method of double jacketing which has been employed.

In order to make the instrument thoroughly accurate, as well as convenient, the inventor has added a base with levelling screws and a simple and efficient method of levelling the lamp, in addition to which he has provided a small piece of glass suitably fixed to reflect the upper portion of the flame visible through the slots, so that its position with regard to the slots may be verified at any time by an observer towards whom the face of the lamp is turned.

The colour of the light is such as to make photometry of ordinary gas lights exceedingly easy; in fact, it is nearly the same as that of the pentane flame, against which no such objections have ever been made on the ground of colour, as have been made in the case of the well-known amyl acetate lamp.

The lamp has been well tested in exposed positions, and has stood the tests remarkably well, the flame resembling a luminous pencil more nearly than an ordinary flame.

Mr. Harcourt pointed out before the Physical Section of the British Association that owing to the employment of an upper and lower cut-off it is impossible to measure distances from any portion of the flame or any point in front of it, so that the law of variation of light according to the inverse square of the distance should exactly hold; but he stated that if distances are measured from a point midway between the axis of the flame and the face of the cut-off the errors from this cause are perfectly negligible at all distances not less than 10in., and he has ensured this point being easily found by making the metal bands which unite the chimney and lower tube of half the width of the cut-off tube, and by cutting two slots in these bands into which a metal plate can be slipped. The lamp can thus be brought into its true position either by setting the edges of the bands when the lamp is at the right height between two plumb-lines lying in a plane perpendicular to the photometer bar and passing through its zero, or by direct measurement from the face of the metal plate.

The work done by Mr. Harcourt towards the production of a thoroughly reliable standard of light and the success which has attended his previous efforts are sufficient guarantee that the new form of lamp will not only prove a thoroughly reliable instrument, but will be found not less accurate than the previous forms invented by him; while the practical experience of the makers of the lamp and their well-known accuracy in the production of scientific instruments will ensure the lamp being so made as to bear successfully the test of everyday work. We may add that this burner can be obtained from the Woodhouse and Rawson Electric Company.

THE ELECTRIC LIGHT IN BRADFORD.

Dr. Hopkinson has now issued his report upon the electric lighting scheme for Bradford. It appears that of the two sites available for the generating plant—one in Bolton-road and the other at the junction of Godwin-street and Sunbridge-road—he has no hesitation in recommending the one in Bolton-road. With regard to the system of lighting, he points out that for central station lighting a variety of systems are available, and after explaining some of them, he says, "We are, then, reduced to the ordinary direct system of distribution. This system presents the advantage that a continuous current is used available at pleasure for charging accumulators or for transmission of power. The direct system may be applied in two ways—either the simple two-wire system or the three-wire system. The latter enables a double potential to be used with the same facility for turning out the lights singly, and it is specially adapted to distribution at such a distance that the mains on the two-wire system become costly, but that it is still not wise to introduce transformers. In the present case, comparing with the two-wire system, the three-wire system would save about 12 per cent. of the electrical power, with a proportionate saving in the cost of engines and dynamos. It would also effect a considerable saving in the cost of conductors. I have therefore no hesitation whatever in recommending its application in the present case. At the same time the distance is not so great that the two-wire system is wholly inapplicable, and if the engineer in charge of the work has a strong preference for postponing the introduction of the three-wire system I would not advise that his responsibility should be diminished by insisting upon its immediate introduction." Dr. Hopkinson adds that the patent for the three-wire system in this country is his own, and that the committee might therefore make such allowance as it thought fit for any possible bias on his part in its favour. If the site in Bolton-road, with its extensive area, were selected, then he would advise the use of Lancashire boilers, with Galloway tubes. Precisely the same consideration would apply in this case as would apply to the boilers for a mill. He thinks that the Lancashire boiler would be adopted for a mill by practical men without the slightest hesitation. With regard to the steam engines, he says that the primary question is—Should the dynamo machines be driven direct with a separate engine to each machine, or should they be driven by belts or ropes from engines running at a slower speed? Dr. Hopkinson considers that a separate engine for each machine is best. Referring to dynamo machines, he says he would incline to the use of five, delivering about 50,000 watts each at the lamps; but, at the same time, the use of a smaller number of larger machines would be perfectly successful, and would possess certain advantages over the larger number of smaller machines. It is very important, he says, that the amount of the electrical supply produced by the machine should be as high as possible, and adds that machines have been built which convert 93 per cent. of the mechanical work applied into electrical work useful outside of the machine. The contractor for the dynamo machines should undertake to give the Corporation a commercial efficiency of at least 90 per cent. Speaking broadly of the system of laying the cables, he points out that there is the choice of three systems. First, the Corporation might use armoured cable—that is, cable protected on the outside by a sheathing of iron wire; they might use pipes of earthenware or iron; or they might lay the cable in brick trenches. Dr. Hopkinson expresses the opinion that the brick trenches would be the best. With regard to the method of charging, he asks is the Corporation to charge by meter or by special agreement with customers. "It is," he says, "very much more costly to store electricity than to store gas, consequently you must provide a plant competent to meet the maximum demand. A consumer, then, who takes his supply for half an hour at the time when the demand is a maximum, will cost you as much as a consumer who takes the same supply during seven or eight hours provided those hours are the hours when the demand falls short of the maximum. You must keep your machinery running, and the only difference between running with a fair load and light is a small addition to your coal bill. Again, although there are many meters which will measure electricity, they are more or less costly, and sufficient time has not yet elapsed to test them for wear and tear. . . . I should therefore advise, at first, at all events, that you should charge by agreement with the customer. The basis of this agreement should be the maximum which the customer will take. You would put an instrument upon his service main which would cut him out if he seriously exceeded his maximum." With regard to the hours of work, Dr. Hopkinson considers that it would be best to begin by running from a little before sundown until perhaps one or two o'clock in the morning. The hours could be extended to an extent justified by the demand. In his judgment the Corporation should not undertake the fitting up of houses for the electric light; but it should keep the most absolute control over the way in which the wiring was done.

The recommendations given above will in all probability be adopted by the Corporation. In order to see the practical working of installations Alderman Fredk. Priestman, Mr. D. Barker, Alderman Beaumont, Mr. R. W. Silson, and Mr. F. W. Hill visited London and Leamington last week, and the result of the visit was that they were confirmed in the opinion that they were about to adopt the best known system for lighting the town. Mr. Shoolbred is proceeding with the plans and specifications, some of which are in an advanced stage. It is hoped that in a week or two the specifications will be placed before the committee, and tenders will then be advertised for. The committee will advertise in detail, with the hope that it may be able to have the work begun and completed, if possible, by one firm of contractors. It is intended to have the work done in such a way that whatever improvements may be found necessary may be made at any time.

LEGAL INTELLIGENCE.

The Faure Electric Accumulator Company (Limited) v. Philippart.

Mr. Justice Hawkins gave judgment in this case on Monday last. He said that the Articles of Association provided that the Board should consist of not less than three directors, of whom two should be a quorum. It appeared that the Board had become reduced to two directors, of whom the defendant was one. These two held a meeting, passed a resolution to increase the Board to five members, named three gentlemen, who at once accepted the position, and the Board thereupon made the second call. It might be that the two directors had no power to reconstitute the Board, but the defendant himself was in the chair when the second call was made and when the shares were forfeited, and he was therefore estopped from disputing the validity of the call so made. In his opinion the defendant had established no legal answer to the claim for unpaid calls, but he had established an answer as to a large part of the interest claimed. There would therefore be judgment for the plaintiffs for the amount of the calls, £49,064, together with interest upon the first call from the 6th December, 1882, until the 3rd January, 1883, the date of the forfeiture, which interest amounted to £204. The judgment, therefore, would in all be for £49,268.—Judgment for the plaintiffs.

COMPANIES' MEETINGS.

The Telegraph Construction and Maintenance Company (Limited).

The twenty-fourth ordinary general meeting of this Company was held on Tuesday at the offices, 38, Old Broad-street, E.C., Sir Daniel Gooch, Bart., in the chair.

Mr. W. SHUTER (the manager) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said : I need not detain you long, gentlemen, because you have the figures before you in the shape of the accounts. I shall be very glad of course to offer any explanation with regard to these figures that you may desire. The work we have done of course represents the profits here, and it includes a considerable length of deep-sea cable. We have also effected some heavy repairs for the Anglo-American Company and the German Union Telegraph Company. You will see from the statement we have made about 8,000 miles of covered wire at the Gutta Percha Works, and I am glad to say that at those works we have been doing very much better business than hitherto. I

Digitized by Google

mean not only cable work but general work in gutta percha, and as that is a general business, I think we may depend that that will continue (hear, hear). The difficulty is for me to make a speech, because I have really nothing to say. I cannot go into the details, of course, of our business—that would not be prudent; but I shall be very glad if there is anything in these accounts you wish to have explained to give you the explanation. I will therefore now move the resolution:—

"*That the report and accounts of the Directors to the 31st December, 1887, submitted to this meeting be and the same are hereby received and adopted, and that a dividend of £1. 16s. a share in addition to the 12s. a share interest or interim dividend paid on June 30th, 1887, be paid on all shares of the Company for the year ended 31st December, 1887, and that such dividend be paid free of income tax.*"

Mr. Philip Rawson seconded the motion.

Mr. Mackay (a shareholder) asked a few questions in explanation of certain items in the accounts, and the Chairman having replied, the resolution was put and carried unanimously.

The retiring Directors and auditors having been re-elected,

Mr. W. Shuter read the following:—The Second Bonus Trust having been closed in June last, the holders of these certificates are requested to send them in, with all outstanding coupons attached, to the Company's bankers, Messrs. Barclay, Bevan and Co., who have about £4,000 of these funds still unclaimed.

A vote of thanks to the Chairman and Directors, proposed by Mr. Mackay and seconded by Major-General Trevor, terminated the proceedings.

The India Rubber, Gutta Percha, and Telegraph Works Company.

The ordinary general meeting of this Company was held on Tuesday last, at the City Terminus Hotel, Cannon-street, Mr. S. W. Silver presiding.

The Secretary having read the notice convening the meeting,

The Chairman said: Gentlemen, you have all a copy of the report. Will you take it as read? (Taken as read.) Then it falls to my lot to move the adoption of the report. It is unnecessary for me to remark that the present state of things is very different in its results from what it has been for many years past. We have endeavoured to explain the causes in the few remarks that we have made in the report. This check to our prosperity we hope is only temporary. I must, however, remind you of the general depression that has prevailed in all branches of trade for several years past, during which time we have been able to distribute an average dividend of 15 per cent. You may depend upon it that no effort will be spared to improve our position, and I am glad to say that the prospects of doing that are encouraging. Though we have increased our returns in general manufactures, thanks to the efforts of those around us, and to additions to our agencies at home and abroad where there is a demand for our products, we have had to meet competition by contenting ourselves with a smaller profit rather than sacrifice quality. The fewness of orders for submarine cables has told doubly against the results of the year. While, on the one hand, we have not made the profit that that department has made in former years, and certain heavy fixed charges have been made which cannot be avoided, we have thereby put ourselves in an efficient state, so as to be ready to execute contracts, and these charges have been thrown upon the other branches of our business. I think it is not too much to expect that electric lighting will shortly come into general use. Now, this branch has occupied a vast amount of anxious attention in order that we may be prepared to meet the demand, however extensive, and here I may say that the works are in all respects in the highest state of efficiency. Under these circumstances, we have had no hesitation in applying some of the profit of the balance of previous years to the purpose for which it was originally intended, namely, towards the equalising of of the dividends, and therefore I beg to move—

"*That the report and accounts be received and adopted, and that a dividend of 10s. a share, free of income-tax, be paid on and after the 29th inst., making 10 per cent. for the year.*"

Mr. Neil Bannatyne seconded the motion.

Major-General Trevor wished before the motion was put to refer to the form of the auditors' certificate. He believed it was usual in commercial undertakings that had reserve funds invested for the auditor to certify to the existence and value of these securities. He would read the form of certificate which a kindred company to this, holding its annual meeting that day, adopted. The auditors there said:—"We have further inspected the several securities held by the company, and the inventories of the various stocks on hand of stores, materials, &c." Now, their auditor did not certify that he had inspected the securities at all. Perhaps it would be more satisfactory if that form of certificate were adopted in future, and when they came to the election of the auditor, he would move that it be an instruction to him to carry this suggestion into effect. The debts owing to the company were nearly £90,000. Did the directors anticipate that any of those were bad debts? He saw that the shares and debentures in other companies gave £9,000 interest, which was rather more than 5½ per cent. So far that was a very fair interest, but he begged to suggest that the nature of the companies in which more than half their reserve fund was invested should be in future stated in the balance-sheet.

Mr. Lamont asked whether there was any probability of the company receiving shortly any orders for cable work.

Mr. Leigh asked whether the 120 miles of cable referred to in the balance-sheet were in stock or in use.

The Chairman, replying to General Trevor, assured that gentleman that the auditor had duly inspected all the securities of the Company. As regarded the nature of those securities the Directors thought it well not to publish it. Mr. Lamont had asked a question that affected all of them. He (the Chairman) could only say that they lived in hopes. As regarded Mr. Leigh's question, he might say that the Company was in receipt of a fair rent for the 120 miles of cable referred to.

General Trevor repeated his question, whether the Directors had any reason to suppose that the item of debts outstanding (£90,000) included any bad debts?

The Chairman: They are all good.

The motion was then put and agreed to unanimously.

On the motion of Mr. Gray, seconded by Mr. Henderson, the retiring Directors (Mr. Silver and Mr. Bannatyne) were unanimously re-elected.

The Chairman having briefly returned thanks,

Sir Wm. Wallace moved and Captain Verey seconded the re-election of Mr. Weise, the company's auditor.

General Trevor moved that the auditor be instructed to add to his certificate, "I have also inspected the several securities held by the Company and the inventories of the various stocks on hand of stores, materials, &c."

Mr. Gray: I think it is impossible for the auditor to do it unless he takes two or three months to go into all the stock, and I question whether it is possible then. We have a very large and varied stock of material at the works. I think the number of articles on the stock list is perhaps 10,000 or 11,000, and each of these articles requires to be valued by experts who know exactly their value.

General Trevor: I meant the value of the securities.

Mr. Gray: I beg your pardon. I have nothing to say about that.

The Chairman: We are quite willing to convey your instructions, but it is effectually done.

The motion as thus amended, having been seconded, was agreed to.

Mr. Moy then moved a vote of thanks to the Chairman, which was seconded by Mr. Treble, and agreed to unanimously.

The Chairman briefly replied, and assured the meeting, on behalf of the Board, that they would always use their best endeavours to carry out the interests of the shareholders.

The Swan United Electric Light Company (Limited).

The fifth ordinary general meeting of the shareholders in this company was held at the Cannon-street Hotel last Tuesday, Mr. J. S. Forbes in the chair.

The Acting Secretary (Mr. Gover) read the notice convening the meeting, and the report and accounts were taken as read.

The Chairman, in the course of his remarks in moving the adoption of the report and accounts, said: Gentlemen, I have to apologise to you for the absence of your able secretary, Major Flood Page, who is now on his way from Berlin, where we sent him on a mission of importance. The report and accounts are short, and, I suppose, the most important and interesting part of the whole thing is to show the position of the Company as a profit-earning concern. If you will take the trouble to refer to the balance-sheet you will find how that looks, and you can do so, as the accounts, happily for you, in this kind of Company, are much less complicated than they are in some other companies with which I am connected. The essential thing in dealing with the accounts is the profit and loss statement, and if you cast your eye down the debtor side I will show you the relative state of things between the year ended the 30th September, 1887, and the year ended the 30th September, 1886. I may incidentally remark that a short time ago we made our year end on the 30th September, instead of the 30th June, for the reason that the Edison and Swan Company of Great Britain, in which you are so very largely interested, only make up their accounts to the 30th June, and when the happy moment arrives for them to distribute a dividend, you will be very large participants in that dividend which will come into the accounts subsequently submitted to you. On the 1st October, 1886, we carried into stock lamps and material of the value of £8,945. I almost think that we promised last year that we would for convenience sake put in the corresponding figures of the previous year, but the secretary does not seem to have made a note of that. The stock carried into stock in the previous year was £10,598, so, in fact, on the year we diminished the stock on hand by the difference. It is an advantage not to have too great an amount of money locked up in stock on hand. We must, however, from the nature of the business have a considerable number of lamps ready for delivery, and as we pay for them as we go on they will appear in the accounts from year to year. The accounts therefore present in that matter a difference in the stock on hand of about £1,600 less. The item of purchases figures at £6,795. That means the gross price of material necessary to produce the lamp—all the glass, the platinum, the carbon, and the many things which go to make up that very small and simple-looking instrument—the raw material. That £6,795 compares with £4,763 in the previous year. The next item I would refer to is the office expenses and wages at factories, and that amounts to £7,839, against £7,932 a year ago. Depreciation is £2,147, against £3,000 a year ago, and the balance of profit for the year is £7,554, against £4,768, so that we have upon the year advanced in respect of profit by nearly 100 per cent. Now we come to the other side of the account, and our sales (less commission and allowances) amounted to £27,128, against £22,016 in the preceding year. We do our business on a principle very well known in Birmingham and Wolverhampton. We have a standard price, and that standard price is diminished according to the number of lamps sold by a fixed discount, and that comes off our standard price. The item of transfer fees, interest, &c., is £1,665, against £1,269, and the stock carried forward into next year is £8,221, against £8,945 the year before. The office expenses, Directors' fees, rent, salaries, &c., have increased to £3,733 from

Digitized by Google

£2,667. Well, to boil all that down, the business has progressed in a fashion which, after charging revenue very liberally with depreciation, increases the profit, as I said before, from £4,768 to £7,554, an increase of about £3,C00, which is a very substantial increase. The capital account is made up of two elements—the element of value represented in a foreign business, of which this profit and loss account is the outcrop, and the element of value made up in the large holding you have in the Edison and Swan Company. You see, by reference to the balance-sheet, that we hold in that company no less than £208,478. Now let me say a word about that company's position. Its business last year showed a profit of £16,000.

A SHAREHOLDER: Upon what capital?

The CHAIRMAN: £471,000, of which £117,000 is in deferred shares. That £16,000 would have been available for paying a dividend upon the "A" shares £85,000, and the "A" shares £267,783—upon, in fact, £350,000. That would be available but for the antecedent history of the Company, the profit and loss account having shown an accumulated loss. It was determined that before there could be any distribution of profit the loss of previous years must be paid off. Therefore that £16,000 was used in order to pay off that loss, which is now wiped off. That is what we propose to do with our balance of profit in this account. We do not propose to distribute it, because we have had to pay down the losses on the working of the concern in previous years. Those losses amounted to £10,000, an amount which has been by the process of applying profit balance from year to year reduced to £5,000 odd; and now we propose to wipe that £5,000 out, and start clear with a balance in our favour for the current year. Therefore, in both companies we have arrived at the moment when we have paid off the encumbrances resulting from losses in previous years, and we are both in the same position this year, namely, that if there be any profit to divide it will be in the discretion of the proprietors to divide it, there being no claim on it in respect of losses in previous years. Concurrently with this there is the fact that in both companies we are progressing in the sale of the article we manufacture. I suppose it is becoming pretty apparent that, notwithstanding the obstruction there is in the way of the electric light by legislation and by litigation as to patents, and by the slowness of the way such things make progress, especially in a country where gas is available at a very low rate, as in England, still it is progressing very rapidly. Every one now hears of installations being put up in theatres, clubs, public buildings, as well as in private houses, and I suppose we may assume now that they will soon spread very rapidly. The difference between the Edison Company in Great Britain, in which you are so largely interested, and the Swan Company abroad, in which you are also largely interested, is this. We have succeeded, as the result of litigation, in establishing our claim to the patents in Great Britain. We have had many fights and one test fight with Messrs. Woodhouse and Rawson of a very important character, and we have won all the appeals. We are at this moment, subject to that decision being overruled, should it ever be tested, the owners of every incandescent lamp in Great Britain. You are interested in that question, because you hold as the Swan United Company so large a stake in the Edison and Swan Company of Great Britain. Abroad, the position is not quite so settled or so advantageous. There we are in litigation, and that litigation has dragged on for a very long time, and has arrived, so far, at no conclusion. There have been decisions adverse, and decisions more or less favourable, but the matter is all *in nubibus*. We still go on manufacturing and selling the lamps, and this is the result of a year's business done under these circumstances. What was it prudent and reasonable to do? We have tried to do abroad what we have done at home with so much advantage, because I will undertake to say that if the Swan Company and the Edison Company had gone on litigating there would have been no such thing as £16,000 last year for the Edison and Swan Company, nor in any year in which such litigation had continued. By putting the horses together we made the Company strong in unity of interests and strong against the rascality of infringers. I was in hopes to-day that we might have been able to announce some sort of treaty or agreement with the foreign companies bringing into life that desirable result, but we cannot do so. We have had in Paris communication with the French Edison Company, who are contesting with us in France the right to make and sell lamps, and in Belgium, Austria, and Russia, and we have come to something like the basis of an arrangement with those gentlemen, under which it is proposed we should become partners in the lamp business just as the Edison and Swan Companies in London became partners in the lamp business—that is, we put all our assets into one pot and divide our profits by agreed proportions. The parties are agreed on that, but unfortunately the Edison people seem to have made some loose arrangement, and the power of the French Company is somewhat interfered with by the application of those agreements. One of the principal litigations is going on in Germany. We hear of the delay of the law in England, and grumble at it. If it is any consolation for you to know it, I may mention that in Germany the delay is something still more awful. There patent cases have been on for three years, and I suppose I can say they seem as far off a decision as ever. We were very anxious to get off this German litigation, as Germany is not far from France, and it is a pretty long frontier. That was one reason for making them partners if we could, so as to have some sort of universal agreement. Major Flood Page is on his way back from Berlin to tell us the result of his interviews with the parties who pull the strings. He went there with the full concurrence of the French Company, and what he is coming back to tell us I cannot say, but from my knowledge of the Germans I believe that they will not at once come into the matter, though probably they will after a little time. If we do succeed in putting the things together I have no hesitation in predicting that it will be very profitable. It all comes to this—is this position satisfactory as against the position that was? I think I have tried to explain it. You are making profits. The profits you have made have paid off your losses, and you start afresh with a considerable amount of profit in hand. You do not owe anything; in regard to the British business your patents have been established, I suppose, beyond all reversal, and the business will increase very rapidly. I think those facts justify the prediction that our Company is in a sound position, and one from which shareholders will reasonably soon reap the benefits which they went in for, and certainly which their patience deserves. In regard to the capital account, there is nothing on the debtor side. The share capital remains the same as before, and amounts to £375,C00. This item, in fact, has really slightly diminished, because the corresponding entry of 1886 was £377,983, and that is explained by the item of forfeited shares, £3,530 against £365 in the previous year. That accounts at once for the diminution. Sundry credit balances is an item amounting to £4,055. Then there is the special reserve against depreciation of plant, £3,000. That is a sum which we took the liberty of taking out of the profit of the preceding year, amounting to £4,768. We thought it better to be secured against contingencies. I explained the matter fully at the last meeting, and we put to reserve out of profit £3,000 in order to meet any contingencies. As I said before, that brings us down to a debit balance on the 30th September, 1886, of £5,834. On the other side of the account you see the old story—the cost of patent rights as put in last year's balance-sheet. I have said before that when people consented to pay so large a sum for patent rights they were simply mad, and our friend, Mr. Swan, was happy in participating, to his very great advantage and that of his friends, in the madness of his fellow creatures. He is a happy inventor, because Mr. Edison is equally eminent, and has not got the solid pudding Mr. Swan has got. It seems a very large sum of money to pay for a patent right, and the cost of the patents would have been much more palatable if ours had been a patent; but, then, we had to spend a large sum of money in order to establish it. Everyone at the outset thought he had got a gold mine in electric lighting. I am not blaming anybody who negotiated the agreement. I am only telling you what the hard facts are. We, however, have got a patent now, and we have it for six years, and during that period we have got the opportunity, if we are as wise and prudent as ordinary tradesmen are, and conduct our business on the lines of ordinary tradesmen, to improve our commodity, and to extend our connections, so that when we emerge from the protection of the patent we shall have established a reputation and obtained a large connection, and a trade mark which will enable us to compete with all comers. Therefore, I am not sure that the cost of patent rights, £105,000, is a very heavy sum to pay. Anyhow, there it is. We have spent in a variety of ways £3,330 during the year, in addition to the £105,000, but we have deducted from that sum 20 per cent. for depreciation, and I think that that is a very liberal scale of reduction, and if it is an error it is in being too much and not too little. Sundry debtors amount to £10,160, of which, I think, about £9,000 were in good book debts at the end of the year. Stock in hand I have explained. From the nature of our business we must keep in stock a very large number of lamps, and those lamps are estimated not at their selling price, but at their cost price in the accounts as an asset, and they represent what in fact are called efficient lamps—lamps ready for sale or order. We merely credit the account with cost price. We then come to our solid pudding—what we have held our grip on out of the subscriptions of the shareholders—on the other side of the account. We have an investment in Prussian Consols amounting to £13,116. We are obliged, being a foreign company trading in Germany, to invest some money in Prussian Consols, and we need only have invested £5,000, but we found, having to do it, that the investment was a desirable one, and we put a portion of our eggs in that basket. Then there is loan on mortgage, £14,300. We lent our partners, the Edison and Swan Company, that sum on a mortgage on the new and beautiful factory at Ponder's End where their business is carried on. That amount, by the way, has since been paid off. Then we have an investment in Consols of about £2,000, and our cash on deposit and in hand amounts to £16,669. I say we have, but I mean we had at the date of the accounts. Therefore you see that you should have a very large amount of money, or assets as good as money, in hand. I think I have exhausted the accounts now; but I want to emphasise this—that but for the unfortunate fact that we had got on our backs the debts of our youth (and as prudent people we could not go on without working them off) we should have had a balance of profit to deal with, but we have applied that balance to writing off those debts once and for all. That will enable us to carry forward into next account a small balance for the benefit of the current year. Having explained all that as fully as I can, and being ready to answer any interrogatories, I now move the adoption of the report and accounts for the year ended 30th September, 1887.

The DEPUTY-CHAIRMAN (Mr. F. R. Leyland): I beg to second that. I wish to express my own strong conviction of the desirability, if we can, of making some reasonable arrangement with our competitors on the Continent, something on the same lines as we have made in this country, and I believe it will be to the interests of the shareholders if that matter is left—at all events for the present—in the hands of the Board to continue the necessary negotiations in the hope that they will bring them to such a point that they will feel justified in placing the matter before the shareholders at some subsequent meeting for their approval and their sanction. If this is arrived at I think we may sincerely say that we shall owe it chiefly to the great trouble which the Chairman has taken in conducting these negotiations, not only in London, but also in Paris, and if they are brought to a successful issue, as I hope they may be, I think we shall have something pleasant to say on that point.

A SHAREHOLDER inquired how long Mr. Swan's salary was to continue.

The CHAIRMAN replied that it was part of the agreement it was to continue for seven years. They bought not only Mr. Swan's patents for what they were worth at the moment, but Mr. Swan's brains for a term of years. That agreement had to run for two years longer. Mr. Swan gave them the benefit of his extraordinary inventive genius, and was always at their call.

Digitized by Google

A SHAREHOLDER asked what interest was received by the Company on the mortgage.

The CHAIRMAN: Four per cent., but the mortgage has been paid off.

Mr. JOHN VERITY thought it must be a source of satisfaction to the shareholders to see that the Company had got through its difficulties. At the time of the amalgamation there were a great many outstanding negotiations and a great many questions unsettled, and having overcome their difficulties, wiped off their losses, and having a small balance in hand to carry forward to the credit of the current year, he thought the Directors ought to receive the thanks of the shareholders. He believed that when they met next year they would have a far more satisfactory state of things to consider. Large central stations were being started in England as well as abroad, and large central stations required a great many lamps. It must also be very satisfactory to them to see that at last they had got rid of all the law suits. He believed that the Swan lamp was very much preferred abroad; but he thought that the Edison interests were very serious rivals to them, and that they ought to amalgamate the interests of the Edison and Swan people abroad. If that were done he believed there would be a much greater chance of an amalgamation being pulled through with the Germans. In regard to Mr. Swan's salary, a contract was a contract, and if they had to pay that gentleman a certain sum annually they must do so; but he thought that Mr. Swan might meet them a little in the matter of his salary, seeing that he had received such a large sum for his patents. He would also like to know if Mr. Swan had been giving his attention to the improving of the efficiency of the incandescent lamp. He noticed that Mr. Leyland was down for re-election as one of the retiring directors, and he did not think there were many present who knew what a large debt they owed that gentleman. He made that remark with all deference to Mr. Forbes, who, he was sure, would agree with it.

Mr. REYNOLDS said he could not agree with the last speaker with regard to Mr. Swan's salary. For his own part he thought that £400 a year paid to that gentleman was a very small sum, and he could only say that if Mr. Swan would join his (the speaker's) firm and transfer his experience to them they would very gladly give him three times as much. He had been glad to hear the remark of Mr. Leyland that he was anxious to see an end put to foreign competition. He had been surprised to hear nothing whatever said with reference to the litigation pending with the Anglo-American Brush Company. The chairman had referred to infringers. If he (the speaker) were rightly informed, the infringement now to be considered was with reference to the Lane-Fox patent, and the infringement the Brush Company contested was on the part of the Company. He would be very glad to hear from the Chairman that they were prepared to do something with the Brush Company in reference to the difficulties that had arisen. The Chairman had stated that the Company's patent would only run for six years, and he (the speaker) noticed that nothing had been written off the value of the patents in the balance-sheet.

Mr. K. HEDGES said he could assure the last speaker that the Swan lamp was the most efficient, and that no one used the Edison lamp who could use the Swan. He thought the Company were to be congratulated on the progress which they had made, and before next year he thought they would be in an extremely satisfactory state, because the number of lamps that would be required for stations would be enormous. The company that used to be the Grosvenor Gallery Company was starting a central station at Deptford, and there were three other companies doing the same thing. He himself was going through the details of another factory where 50,000 lamps would be required, and that brought up the number required for these central stations to a quarter of a million.

The CHAIRMAN, in reply, said he was very glad indeed that a discussion had taken place, because they had had the opinion of three gentlemen eminently well qualified to advise them. In regard to the remarks of Mr. Reynolds, he would only say that after immense litigation the Company had got their patents protected, and they were willing and determined to rest on those decisions. It was competent for the public to call on the Company to supply either Swan or Edison lamps, and they did, in fact, for a time supply those lamps at discretion. They could get the lamps from Mr. Edison on terms rather less advantageous to them as a matter of profit and loss than their own lamps, but they could supply the Edison lamps. When the public had the opportunity of getting a Swan or Edison lamp it was a pretty good test of the relative value of the two that the demand for the Edison lamp had died out, the whole demand being for the Swan lamp. That was a pretty good illustration as to what was considered the best lamp, and that they found was rather an important factor in the negotiations abroad, because the men who were fighting for their own hands said that one of the chief inducements they had for coming to an arrangement was the superiority of the Swan lamp. In virtue of that they were prepared to make concessions which at first they would not listen to. He had had the opportunity of listening to all that Mr. Sellon could say on the position of the Brush Company, and all that Lord Thurlow could say, but they had not been able to agree to the views of those gentlemen. Everything they had said about their case had been said by Messrs. Woodhouse and Rawson and other infringers, and when he used the word "rascally" infringers in his opening speech he did not mean honourable gentlemen who imagined they had a patent but had not—he meant piratical infringers who had no patent. He had contended both with Lord Thurlow and Mr. Sellon that the Brush Company had nothing to sell. The company must rest on their patents and on the protection which those patents had given them. If Lord Thurlow were to persuade the directors to throw away some of the interests of the company there would be plenty of others who would endeavour to obtain the same concession. The litigation was going on, and he would ask Mr. Crisp to explain how it stood.

Mr. CRISP said that the general position of the litigation with the Brush Company was this: they were proceeding against that company on precisely the same lines as they had proceeded against Messrs. Woodhouse and Rawson. In that action exactly the same issues were raised. No new fact had been brought forward by the Brush Company which had not been fully thrashed out in the action with Messrs. Woodhouse and Rawson. There was a second action brought against them by the Brush Company as to their lamp, over which they had a great deal of anxiety to discover what possible ground there was for bringing the action. One of the actions was expected to be settled in a month, and the other next week.

A SHAREHOLDER said he observed that the Company held Edison and Swan shares to the amount of £208,478. He assumed that that was the nominal value, but could the Chairman give the shareholders any idea of the market value?

The CHAIRMAN said that he was not himself in the habit of watching the market. He should think that the proper value of the shares was the amount at which they stood in the assets. He did not always find the Stock Exchange value of a thing was its proper value.

He then put the motion, and declared it carried unanimously. Continuing, he proposed the re-election of Mr. Leyland, remarking that, as Mr. Verity had said, the Company owed a very great debt of gratitude to Mr. Leyland, who had pulled the leading oar in their boat.

Mr. QUILTER, M.P., in seconding the motion, also testified to the valuable services which Mr. Leyland had rendered to the Company. Any success which the Company had had had been very largely contributed to by Mr. Leyland. With regard to the question which had been asked as to the value of the £208,478, which they held in the shares of the Edison and Swan Company, he could not give any detailed information on the subject, for the reason that the shares were not quoted in the official list, and he was not aware of any transactions having taking place in those shares on the London Stock Exchange. Whatever might be the present value of the shares, he thought that, in view of what the Chairman had said, it was obvious there must be a large increase in their value should they ever be quoted.

The CHAIRMAN having put the motion, which was carried unanimously, moved the re-election as a Director of Mr. Quilter.

Viscount ANSON seconded the motion.

Mr. SWAN said he would like to make a few remarks in reference to the observations which had been made by Mr. Verity. That gentleman had spoken under the impression that he (Mr. Swan) had practically disconnected himself altogether from the progress of electric light invention, and more particularly from the lamp. That, however, was an entire mistake. He was continually working one way or another upon matters which he believed would be beneficial to the Company, and so far as his lamp was concerned, he had done very much he thought to help forward its improvement. Quite recently the Company took out a patent which he believed would be of value in connection with the improvement in the incandescent lamp. He was always working one way or another for the benefit of the Company, and he was always at their service. There was one point which he thought ought to be remembered by those who might be inclined rather to grudge the small payment which was made to him, and that was that when the undertaking was first formed he did not offer his services to the Company. They were sought, and it would have been very much more in accordance with his own wishes if he had been left entirely free, and had not been solicited to occupy the position of a Director of the Company. If he had done so he was sure it would have been very greatly to his pecuniary advantage, for the consequence of his joining the Board of the Company was that he had to leave a lucrative business in Newcastle.

On the motion of Mr. HARVEY, seconded by Mr. BEAUMONT, Messrs. Quilter, Welton and Co. were re-elected auditors.

Mr. VERITY then proposed, and Mr. REYNOLDS seconded, a vote of thanks to the Chairman and Directors.

The CHAIRMAN, in reply, expressed his acknowledgments, and said he was sure that the compliment which had been paid them was appreciated by his colleagues as much as by himself.

The proceedings then terminated.

The Telephone Company of Egypt (Limited).

Report of the Directors for the year ended 31st December, 1887, to be presented at the fifth ordinary general meeting of the Company, to be held at the offices of the Company, 14, Austin Friars, on Tuesday, the 6th March, at 12 noon.

The amount of revenue accrued for the past year exceeds that of the previous year by £498. 18s. 10d.; the working expenses have, however, been heavier, due to a large extent to reconstruction of some of the lines, the cost of which has been charged against revenue.

After writing off a sum of £219. 9s. 5d. for depreciation, the net profit for the year is £3,844. 0s. 4d., and including £442. 8s. 2d. brought forward from the previous year, there is available for distribution £4,286. 8s. 6d. Out of this the Directors propose to pay a dividend of 6 per cent. for the year on the preferred shares, which will absorb £3,621. 6s., and to carry forward £665. 2s. 6d.

The dividend now proposed will be applied in payment of the arrears of cumulated interest to 31st December, 1885, which will thus be finally discharged, and dividends hereafter declared will belong to the years for which the accounts are rendered.

The past year has been marked by the opening of two small exchanges at Zagazig and Mansourah, and the Directors believe that there is room for still further development in this direction.

Permission has lately been granted by the Government for an extension of the system to Hélouan, and a trunk wire connecting Cairo with that place—distant some 16 miles—is now in course of erection. A royalty will be payable to the Government on the gross revenue of this branch in consideration of the permission accorded.

Digitized by Google

The Directors deeply regret to have to record the death, after a very short illness, of Mr. A. D. Evans, the Company's late manager in Egypt, which took place at Brighton on the 15th October last. The success which has characterised the operations of the Company in Egypt has been largely due to the assiduity with which Mr. Evans conducted the business.

The following figures show the progress made by the Company since its formation:—

	On 31st December				
	1883.	1884.	1885.	1886.	1887.
Total number of subscribers in Egypt	454	547	714	817	917
Gross revenue	£6,400	£7,014	£8,650	£9,400	£10,000

In order to liquidate the loan from the Oriental Telephone Company (Limited), and to provide for working capital, the Directors propose to create 6 per cent. debentures to the extent of £20,000, and to issue £10,000 thereof. In terms of the Articles of Association, a resolution to that effect will be submitted for your approval.

The Director who retires on the present occasion is Mr. H. Grëwing, who being eligible, offers himself for re-election. Messrs. Price, Waterhouse and Co., the auditors of the Company, also retire, and offer themselves for re-election.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts for the week ended 24th February amounted to the sum of £4,643.

LANCASHIRE AND CHESHIRE TELEPHONIC EXCHANGE COMPANY.—The directors have declared an interim dividend at the rate of 7 per cent. per annum, being the same as last year.

WEST AFRICAN TELEGRAPH COMPANY.—The half-year's interest due 1st inst. upon the Five per Cent. Debentures of this company will be paid at the National Bank of Scotland, Nicholas-lane, on and after that date.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this company for the week ended February 24th, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,750.

NEW COMPANIES REGISTERED.

THE BOURNEMOUTH ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—Registered by Peacock and Goddard, 3, South-square, Gray's Inn, under Table A. Capital £4,000, divided into 800 shares of £5 each. Object, to supply approved renters in the town of Bournemouth and its neighbourhood with electric light and power, and to carry on the business of an electric light and power company in all its branches. The first subscribers are:—

	Shares.
F. J. Bright, bookseller and stationer, The Arcade, Bournemouth	1
J. Denkin, architect, Bournemouth	1
J. J. Allen, house furnisher, The Quadrant, Bournemouth	1
H. Hammond, draper, Bournemouth	1
P. W. G. Nunn, physician and surgeon, Bournemouth	1
C. P. Fippard, cook and confectioner, Bournemouth	1
J. S. Helyer, architect and estate agent, Bournemouth	1

GULCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY.—This company is formed for the purchase of the goodwill, patents, plants, materials, stock-in-trade, contracts, and other property of the Gülcher Electric Light and Power Company (Limited). The capital is £70,000 in 70,000 shares of £1 each, of which 50,000 are 10 per cent. preference shares, and 20,000 are deferred shares. The business is acquired in consideration of a payment of £16,000 and 20,000 deferred shares to the liquidator of the old company. The present issue is of 25,000 preference shares.

NOTTING HILL ELECTRIC LIGHTING COMPANY (LIMITED)—Registered by Loughborough and Gedge, 20, Great Winchester-street, E.C., with a capital of £100,000 in £10 shares. Object, to light public or private buildings, places, or property with electric light, and to undertake the supply and application of electricity or force generated or produced by or by the aid of electricity, for any public or private purpose. The first subscribers are:—

	Shares.
S. Waters, 24, Ladbroke-square, W.	1
J. T. Jarvis, 30, Ladbroke-square, W.	1
W. Crookes, 7, Kensington-park-gardens, W.	1
J. Crookes, 7, Kensington-park-gardens, W.	1
A. Howden, 72, Holland-park, W.	1
F. Radford, 26, Pembridge-gardens, W.	1
A. Webb, 13, Lansdowne-crescent, W.	1

The number of directors shall not be more than ten nor less than three, and the first shall be William Crookes, Aston Webb, Francis Radford, Alexander Howden, James Thomas Jarvis and Sidney Waters.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 512.—Vol. XX. FRIDAY, MARCH 9, 1888. Price 4d.

NOTES.

It is sometimes said that figures can be made to prove anything; but it would be a difficult task to manipulate the figures presented last night by Mr. Treuenfeld so as to *disprove* the conclusion that an enormous amount of property has been preserved from destruction by the system of fire telegraphs, and also that every year a vast amount is still lost which might be saved by an adequate provision of these safeguards. It is simply astounding to learn that there are at the present time only seven towns in this country that have adopted the system of street fire-alarm posts. The results of this negligence—for by no other term can it be described—are shown in the most decisive way by the statistics brought forward by Mr. Treuenfeld. To quote only one example, in Hull, where there are no street fire-alarms, during the period 1881-1886, the percentage of "serious" fires to total calls was as high as 64·1; while in Glasgow, where Anderson and Munro's street fire-alarms were adopted in 1879, the ratio of "serious" to total fires since that date has averaged 1·1 per cent. Of course there are many other things to be taken into consideration in contrasting Glasgow with Hull, but it is impossible to overlook the absence of a proper system of alarms. The subject is one of the highest possible importance to the community at large, and it is difficult to understand in what way the local authorities can better expend their revenues than in the provision of this inexpensive and effective means of insurance. A copy of Mr. Treuenfeld's paper will, we hope, be sent to every important municipality throughout the kingdom; if this be done, we have little doubt that it will result in a large extension of fire telegraphs, and a corresponding diminution in the loss of life and property from fire.

We give this week the first portion of Capt. C. E. M'Evoy's description of electrical appliances for submarine mining to which we referred in our last issue. The extreme ingenuity and skill with which the details have been worked out can scarcely be fully appreciated without a personal examination of the apparatus. Two problems of equal importance have to be solved in these cases; first, to ensure that the mines shall not be exploded prematurely or unintentionally, and, secondly, that they shall infallibly explode when required. So far as human skill can provide, each of these essentials is fully attained by Capt. M'Evoy's apparatus. When the firing position is arrived at, and before the insertion of the firing plug can bring about the final result, both eye and ear are appealed to in such a way as to render a mishap due to carelessness almost absolutely impossible.

We are glad to see that the *Army and Navy Gazette* has this week an article on "Submarine Miners," following up much the same line as was adopted by ourselves four months ago. The necessity for the creation of additional volunteer corps for the protection of the mercantile ports is fully recognised. It is of course assumed that the rank and file should consist chiefly of sailors or naval reserve men, but the assistance of technical officers is admittedly indispensable.

In our continuation of the report of the recent discussion at the Society of Telegraph-Engineers will be found a diagram of the interesting experiment recently carried out by Mr. Mordey in order to get a visible indication of the difference of phase between the primary and secondary currents of a transformer. This has suggested to us the possibility of "seeing" the lag due to self-induction in a somewhat more direct manner. The experiment would only be useful for lecture purposes, as it could not be made with a closed magnetic circuit transformer, and we give it merely for what it may happen to be worth. It is well known that if the vibrating make-and-break of an ordinary induction coil is looked at by the light of a Geissler tube, placed in the secondary circuit of the same coil, the vibrator appears, for obvious reasons, to be absolutely at rest. But the moment of illumination of the tube may be retarded in reference to the phase of the vibrator by varying the amount of inductance in the external circuit of the coil. Consequently, by placing an inductional resistance in series with the tube, it may be expected that the apparent position of the vibrator will change. If the external resistance takes the form of a solenoid with a movable iron core, then, on moving the core slowly to and fro, we should expect to see the vibrator apparently moving in unison therewith. It would be easy, if necessary, to arrange a mechanical device to exaggerate the apparent motion of the vibrator. We hope that the simplicity of the experiment will induce some of our readers to try it.

From a paper which we publish in this issue it will be seen that Dr. Fleming has determined the specific resistance of manganese steel, and finds it to be 3¼ times as great as that of German silver. Next week we shall give some determinations (by Mr. Mordey) of the specific resistances of several

Digitized by Google

new alloys. Amongst these occurs a certain alloy of copper which has a resistance very nearly equal to that of manganese steel, with a much lower temperature coefficient.

WITH regard to the utilisation of wind power for electric lighting we may mention that Sir DAVID SALOMONS, some years ago, planned an installation of this character for 150 lamps, or 300 with accumulators, and he has kindly furnished us with the estimate which he obtained. It will, however, be remarked that the number of lamps proposed was somewhat large for an installation of this class. A set of windmill gearing, including 65ft. iron support, shafting, and governor, to indicate 15 horse-power with a 20-mile wind within 10 per cent. of regularity (and nothing better can be done by the best governors made), would cost £1,160. The foundations would have cost quite £150 more. For dynamo and gearing, including a special governor to compensate the 10 per cent. speed variation, another £250 might be added—total £1,560, or over £10 per lamp, without accumulators. We believe, however, that the Glasgow installation, to which we recently alluded, does not comprise more than 10 or 12 lamps.

ALTHOUGH the recent "Convention" of the American Edison Companies at Chicago was held with closed doors, our New York correspondent was enabled in our last issue to give some very interesting details of the proceedings. From this it will be seen that an important move is likely to be made in raising the standard voltage of the Edison system from 220 to 330 volts. Whether this is to be effected by an advance from a three-wire to a four-wire network, or by the substitution of 165-volt lamps for the present 110-volt type, we are not told, though the former is perhaps more probable. The fact that Edison, overcoming his "almost invincible repugnance" to appear in public, addressed the meeting in person, is evidence of the importance attached to the occasion.

ON this point we are enabled to add some further information derived from an independent and thoroughly authentic source. It appears that about twelve months ago several important local companies working the Edison system in America found that they had practically arrived at the end of their tether—that is to say, they had completely covered the ground within the limits of the three-wire 220-volt system, and, unless they could extend the economical radius of distribution, the output could not be further increased. Whether or not they had in all cases arrived at the limit of 20,000 lamps, which Mr. GORDON holds to represent the maximum economical output for a single station, we cannot say, though a maximum current of 9,000 amperes mentioned by our correspondent represents about 36,000 lamps, and might mean nearly 50,000 wired. However this may be, it appears that under the aforesaid circumstances a strong disposition was shown to introduce alternating currents for the supply of the outer circle, and a memorial was presented to the parent company in favour of such a step. But although the movement was strongly supported by several of the leading men connected with the system, Edison himself set his face against it from the first. We may believe that it was this agitation which recently led Edison to rake up his earlier patents with motor-generators, and to lay down the experimental plant of this type, which is now running at Llewellyn Park (see *The Electrician*, October 14th, 1887). We have yet to learn how much success the latter system has attained, but it is tolerably evident that it has not yet emerged from the experimental stage. It is also evident from our correspondent's letter that Edison has succeeded in stemming the movement which had set in amongst his supporters in favour of alternating currents. Probably the enormous increase of business from the transmission of motive power had also a good deal to do with the decision to stand by the continuous current.

IN the light of these and other facts it is, however, not a little singular to find that Mr. CROMPTON, in this country, is perfectly content to abide by a simple parallel distribution. On this point we find that some misunderstanding exists as to the nature of the installation at Kensington Court. We may therefore state that—unlike Mr. CROMPTON'S Vienna installation—the batteries used at Kensington Court are confined to the generating station, and the distribution in the mains is entirely at low tension. The batteries are employed solely in order to enable the machines to work for a shorter period, and not, as in the B.T.K. system, to increase the efficiency of the distributing mains. It will therefore be seen that Mr. CROMPTON'S advocacy of the continuous current is of a remarkably uncompromising—in view of the rise in copper we might almost say of an heroic—character; and although we expressed last week our concurrence with much that Mr. CROMPTON urged in his recent speech at the Society of Telegraph-Engineers, we have yet to be convinced that it is wise to relinquish the advantages offered by multiple main distribution.

THE most satisfactory feature in the report of the Anglo-American Brush Corporation (whose annual meeting is reported in another column) is undoubtedly to be found in the evidence which it affords of the large increase in the volume of business transacted during the last twelve months. This is only a confirmation of the general impression that a genuine revival of electric lighting business has set in. The corporation has done well to recognise the desirability of enlarging its field of operations by the adoption of alternating-current plant. And we think that the expressions of satisfaction made use of by the Chairman in speaking of the transformer and the alternating-current dynamo designed by Mr. MORDEY will be found to be fully justified by the issue. The Mordey transformer is already familiar to our readers from the recent proceedings of the Society of Telegraph-Engineers. The dynamo, which we hope shortly to describe and illustrate, will be found to embody a decidedly novel departure in the construction of alternating-current machines.

MONDAY night's discussion of the Electric Light Amendment Bill in the House of Lords revealed not merely a fairer appreciation of the merits of the Bill, but a more candid esti-

Digitized by Google

mate of the demerits of local authorities. There could be no mistake about Lord SALISBURY'S remarks on the danger of creating irresponsible corporate bodies on the pretence of placing them under the control of local authorities. The experiment has not proved wholly satisfactory, the gas and water boards being chiefly notable for their independence and extravagance. It may be anticipated, however, that long before the 42 years' life of a provisional order has run out the local authorities will be better fitted than they are at present to take over the business of electric lighting.

THE POSTMASTER-GENERAL'S declaration with regard to the purchase of the telephone companies by the Government conveys precisely what we have asserted all along, namely, the fact that no such project has been under consideration, or is even contemplated. Many persons will be aggrieved by this answer, but they cannot charge it with indefiniteness. It is much to be regretted, however, that it was not made earlier.

WE have been favoured with a communication from Mr. GEORGE QUARRIE, who writes: "As other prints will probably refer to the following matter, I give you a like opportunity, merely adding that you are at perfect liberty to treat the same as you please." Of course we feel very grateful, and will proceed to avail ourselves of the liberty which is so kindly accorded us. Mr. QUARRIE is not altogether unknown to fame, if indeed he is the gentleman of the same name who once proposed to provide electricity *ad lib.* by laying down an iron floor upon the roadway and utilising the vibration of the passing traffic by means of suitable electro magnets. It appears, however, that Mr. QUARRIE has now turned his attention from practice to theory, and in the communication before us he offers a reply to the ever interesting question "What is Electricity?" "Electricity," says Mr. QUARRIE, is "Nature's vacuum." This seems simple enough at first sight, though we are a little puzzled at reading further on that "All matter is visible and tangible only by virtue of the electricity it contains." A visible and tangible vacuum is a conception by no means without a certain degree of merit. At the end of the paper we learn that Mr. QUARRIE anticipates that his discovery will lead to "a means of providing cheaper current electricity." But on the whole we think the iron roadway scheme the more hopeful of the two.

UP to the time of going to press our New York correspondent's letter had not come to hand. The principal electrical news from America—apart from the Pittsburg Convention, which we deal with elsewhere—appears to be the announcement that Edison is about to bring out a new type of incandescent lamp, having a standard consumption of 3·1 watts per candle-power. The 16-candle power lamps will range from 90 to 125 volts. This is for use in isolated plants. For central station lighting a 150-volt lamp, with specially long filament, has been designed. The filament makes three distinct spiral twists. For use with secondary batteries, lamps of 60, 40, and 20 volts, running at 2½ watts per candle-power, and giving from 10 to 30 candles, are promised shortly.

Weston-super-Mare.—The Town Commissioners have finally decided to postpone the question of lighting the town by electricity for the present.

Taunton.—At a meeting of the Lighting Committee of the Town Council of Taunton it was unanimously decided to recommend the Council to provide thirty additional arc lamps for public lighting of the streets.

Electric Communication in the House of Commons.—It is proposed to establish electric communication between the Library and the House, so that members in the Library may know who is addressing the House.

Dumbarton.—The extensive ship-building yards of Messrs. William Denny and Brothers, at Dumbarton, are to be lit throughout by electric light. Inquiries are now being made amongst the leading electrical firms.

Vienna.—A new patent law is under the consideration of the Government.—The Electrotechnical Institute of Vienna is carrying out a series of tests of accumulators. The Julien, Reckenzaun, and Scheneck-Farbaki types are under consideration.

Cheltenham.—An installation of one arc and sixty incandescent lamps has been fitted up for a tradesman in one of the chief streets of Cheltenham by the Walsall Electrical Company. A Crossley 4 horse-power nominal gas engine and a set of storage cells are employed.

A New Scientific Society.—It is announced that a new scientific society has been formed in Paris, to be called the Société Magnétique de France. The *Journal du Magnétisme* is to become the official organ of the new society, and its offices are at 5, Boulevard du Temple, Paris.

Royal Institution.—At the general monthly meeting of the Royal Institution, held on Monday, March 5th, Edward Woods, Esq., M.Inst.C.E., Vice-President, in the chair, the special thanks of the members were returned to Prof. Dewar for a donation of £100 to the fund for the Promotion of Experimental Research.

The Electric Lighting of Terni, Italy.—The lighting of this town by electricity was commenced on the 12th ult. The motive power is furnished by three turbines of 160 horse-power each, made by Ganz of Buda-Pesth. Each turbine drives a Zipernowski dynamo. The total number of incandescent lamps is 300.

Electrical Organ at the Barcelona Exhibition.—The local paper, *El Barcelonés*, of March 2, states that the Palace of Fine Arts at the Barcelona Exhibition is to be furnished with an electrical organ constructed by Dr. Aquilino Amezua. It is stated that the organ will be in three distinct parts, each communicating with the key board by electric wires.

Glasgow.—The *Glasgow Herald* understands that steps were taken last week in Glasgow to form a company for the manufacture and sale of electric current there on the same lines as those in London. As Glasgow is a city of fewer burning hours than London, it is proposed to utilise the spare time of the plant there for driving machinery during the day.

The Italian Exhibition and the Electric Light.—According to advices from Rome, the coming Italian Exhibition which is to be opened at Earl's Court in May next is to be lighted by the electric light by an Italian firm. The *Bollettino delle Finanze, Ferrovie e Industrie* of March 4th says that the undertaking has been confided to Messrs. A. Belloni and Co., of Milan.

Digitized by Google

Madrid.—The *Avenir Financier* states that at an extraordinary meeting of the Telephone Company of Madrid, it was decided to increase the capital from 1,200,000fr. to 1,800,000fr. by the creation of 1,200 shares of 500fr. each, upon which 250fr. is to be paid up. This increase of capital from £48,000 to £72,000 is said to be rendered necessary by the expansion of the company's business.

Electric Lighting of the ss. "Oonah."—On Tuesday the electric light was put into operation in the fine new screw steamer "Oonah," built to the order of the Tasmanian Steam Navigation Company by Messrs. A. and J. Inglis, of Pointhouse, and constructed under the superintendence of Mr. H. R. Robson, the company's agent in this country. There are in all 165 lights, representing an installation of 2,460 candle-power.

The United States Telegraphs.—A Washington telegram says that the Post Office Committee of the Senate has decided to report the Bill for regulating the Inter-State telegraph system on a plan similar to that which obtains with regard to the railway system. The Bill contains a clause prohibiting the telegraph companies from making a larger charge for messages sent over a short distance than over a long distance in the same direction.

The Telephone Companies and the Government.—In the House of Commons on Tuesday last Mr. Provand asked the Postmaster-General if there was at present any scheme for the purchase of the telephone companies' interest being considered by the Government. Mr. Raikes said that no scheme was being considered by the Government for the purchase of the telephone companies' interest, nor was any such scheme in contemplation.

The Schanschieff Battery.—On the occasion of the opening of the new line of the London and South-Western Railway to Bournemouth several of the saloon carriages in the first train which ran over the line were lit by means of the Schanschieff battery. Great interest was manifested in the light, and we believe that several railway directors expressed their intention of recommending its adoption. We learn that similar lamps are being made for other companies.

Mill Fires in America in 1887.—The annual report of the Manufacturers' Mutual Fire Insurance Company for 1887 contains a record of 167 fires occurring in mills. The report states that the company has done all in their power to encourage electric lighting as being the safest of all artificial lights, and that "a very large number of mills are so lighted." But amongst the list of fires not one is known to have been produced by electric lighting apparatus.

Copper.—Imports of copper into the United Kingdom for February show an increase in value of £395,000, compared with those of February, 1887, and the increase for the past two months is £760,000. At the same time the deliveries to the trade have been much curtailed, and accordingly the stock of copper accumulates. At present advanced prices the amount locked up in the financing of this copper operation must be already reckoned by millions, dipping heavily into the resources of the French banks engaged in it.

Paris.—The Municipal Council are considering a scheme for lighting the whole of Central Paris by electricity, and it is hoped that the work will be completed in time for the Universal Exhibition. A report on the subject has been handed in by M. Lyon Allemand to the Council, and it is proposed in that document that there should be a large municipal machine room under the Central Markets, with wires extending through the metropolitan sewers to the main boulevards and other important arteries.—The Paris Morgue is to be lit by electric light.

The Electro-Harmonic Society.—The first Amateur Concert of this Society was held in the banquet room at St. James's Hall on Friday last, and, in spite of several unavoidable changes in the programme announced, was an unqualified success. In place of Mr. Swinburne, who was to have rendered two pianoforte solos, but who was unfortunately called away on business, the gap was filled by Mr. Gatehouse, who played a violin solo, and Mr. Alfred Izard, the accompanist to the society. Mr. T. H. Harrison was also unavoidably absent, and his place was taken by Mr. J. N. Clarke.

Extract from the Proceedings of the Electric Light Convention at Pittsburg.—"Mr. Smith: I would like to ask Dr. Moses what would be the effect upon the ship of demagnetising the compass. What mischief would it do?—Dr. Moses: The result would be that the ship would float around indefinitely; and when they were thinking that they were going to do most they would find the needle following the movement of the ship, and going round as any needle would if you blow upon it. If, for instance, you attempt to float a needle upon water, and come close to it, you will find it darting off like bacteria in all directions."

Kensington.—At the last meeting of the Kensington Vestry, the following resolution, moved by Mr. John Braye, was carried, and referred to a committee to report:—"That this vestry, in the interest of public safety and economy, apply to the Board of Trade for a license, under the Electric Lighting Act of 1882, for the right of supplying the whole parish of St. Mary Abbotts, Kensington, with electricity for lighting and other purposes, and for power to transfer or lease any portion of the rights and privileges conveyed by the license."—The House-to-House Electric Lighting Company has applied for a provisional order for this district.

The De Khotinsky Incandescent Lamp.—These lamps are now made of the following types:—From 5 to 200 volts, from 4 to 300 candle-power, and to work at a consumption of from 5 to 2¼ watts per candle. So far as we know these are the only lamps at present attainable to work at so high a potential, and we learn from the makers that lamps of very small candle-power are now being made for 200 volts. The life of the lamps is stated to vary from 300 hours at 2¼ watts per candle, up to 2,000 hours at 5 watts per candle. Since the month of August last there has been at work in Berlin an installation of 1,100 lamps at a potential of 150 volts.

Dublin.—A lecture was delivered at Brown-street Schoolhouse on Tuesday evening by Mr. Joseph Farrar, of the Telegraph Department, G.P.O., on "Electricity and Magnetism," accompanied by experiments, in aid of the building fund. The school was fitted up with telephones, electric bells, electric lights, and telegraphs. Amongst the latter was exhibited a recent invention of Mr. Louth, chief engineer (Dublin), which has not yet been made public, but of which he kindly gave Mr. Farrar the use. The lecturer explained the working of electric lights, pumps, electric propelled tramways, &c., and was listened to with the greatest attention by a crowded audience.

Belgian Telephones.—*L'Etoile Belge* says:—"Two new telephone companies have been formed, one in Rosaria, with concession for the Argentine Republic and Uruguay; the other one in Cadiz. This is a double success for Belgium, since these companies, after comparative examination of all telephonic apparatus for subscribers, have adopted the one constructed by Messrs. Mourlon, of Brussels. It is perhaps of all the products of the Belgian industry the one which has the

Digitized by Google

most extended market, being used not only in America but also in China, Japan, and even in the Congo, where the network in San Thomé Island has no apparatus but those of this Belgian firm."

Buckingham.—The Buckingham Flour Mills, belonging to Mr. A. C. Rogers, have been fitted with electric light. The dynamo is of the Elwell-Parker type, and is driven by water power from the mill shaft. Edison-Swan incandescent lamps of 16 to 20 candle power, which are used, are fixed in white enamelled metal shades set close to the ceiling. There is also a movable lamp fixed in a lanthorn, which by means of a flexible silk-covered wire cord may be used for stone dressing, examining the machinery of the mill, and also to illuminate the bins, where a light is not always required. The contract has been carried out by Mr. W. Habgood, electrical engineer, West Dulwich.

The Lighting of the City.—At a meeting of the City Commissioners of Sewers, on Tuesday last, a report was brought up from the Streets Committee, recommending that the proposed contract with the Anglo-American Brush Electric Light Corporation for lighting a district of the City by means of electricity be not further proceeded with. Mr. Bridgeman moved the adoption of the report, stating that the recommendation of the committee was in consequence of the opinions expressed at the previous meeting of the court. Mr. Treloar expressed a hope that electric lighting would be adopted in the City. Mr. Harris, Mr. Bell, Mr. Morton, and other members, having spoken briefly, the report of the committee was agreed to.

The Lighting of the Melbourne Exhibition.—The forthcoming International Exhibition to be held at Melbourne will be lighted by means of 800 Brush arc lamps of 2,000 nominal candle-power, and about 3,000 incandescent lamps of 17 candle-power, operated by thirty-seven No. 7L Brush dynamos and seven E2 Victoria machines. The Anglo-American Brush Electric Light Corporation have just contracted with the Australasian Brush Electric Light Power and Storage Company for the supply of the whole of the dynamo machinery and arc lamps required for this extensive installation, and have undertaken to ship all the apparatus by the end of the first week in May.

Exports of Telegraphic Wire, &c.—The Board of Trade returns for last month and for the two months ended 29th February, which have just been issued, show a considerable falling off in our exports of telegraph wire, and of apparatus classed under that category. The following are the values for the first two months of this year, in comparison with the corresponding returns for the two previous years :—

Exports of Telegraphic Wires and Apparatus connected therewith.

	1886.	1887.	1888.
January	£68,623	£14,442	£41,231
February	19,286	44,137	14,051
Two months	£87,909	£58,579	£55,282

Society of Arts—Lectures by Dr. Oliver Lodge.—A short course of lectures on "The Protection of Buildings from Lightning," by Prof. Oliver J. Lodge, F.R.S., to be delivered under the title of the Dr. Mann Lectures, as a memorial of the late Dr. Mann, will be commenced on Saturday afternoon, the 10th inst. The course will consist of two lectures, the first of which will take the form of a slight historical sketch, and will call attention to the outstanding questions, difficulties, and points of controversy in connection with lightning conductors. At the second lecture experimental answers will be given to some of the questions raised, and an endeavour will be made to supply a more complete account of the liability of conductors to side-flash than has yet been attempted. The chair will be taken at 3 o'clock.

Death of a French Electrician.—The Paris correspondent of the *Daily News* telegraphs :—M. Richard, the civil engineer who laid down the first network of telegraphic wires in France, died this morning. When the investment of Paris became inevitable he organised the telegraphic service at Tours in the month of August, 1870. He also laid down so stealthily a wire in the Seine, connecting Havre and Paris, that not half-a-dozen persons suspected its existence. One of these was a peasant, who went and told the Germans that he knew a military secret of the utmost importance, which he could let them have for 5,000f. They gave him the money, but told him that if he was fooling them they would not only take it back, but shoot him. After the war his traitorous act, about which he talked, was denounced, and he was brought to trial and punished. M. Richard of late years was Government expert for all telegraphic and telephonic experiments.

Leamington.—At the last meeting of the Leamington Town Council a correspondence was read between the town clerk and the Midland Electric Lighting Company, in which the company requested to be paid for the street lighting which they were then carrying out. This was refused, on the ground that the terms of the contract had not been complied with. In the course of the proceedings the room was suddenly plunged in darkness owing to a failure of the light. The mayor (Mr. Fell) explained that the mishap arose from five of the six dynamos having been rendered useless by the recent short-circuiting, involving the Midland Electric Lighting Company in a loss of £1,500. The company were, he said, doing their best to remedy the defects, and would have three or four dynamos in operation by the end of the week. Mr. Orton submitted a proposition to give notice to determine the contract if the lighting of the Parade by electricity was not considered to be satisfactory by the 31st of March. The mayor asked Mr. Orton to defer his motion for a month ; and suggested that at the end of that time, if the electric light was not a success in the town, the necessary 12 months' notice might be given to determine the contract. This suggestion was adopted.

The National Telephone Company.—We have received a copy of this company's list of subscribers for the Yorkshire district. The book contains a very interesting plan, showing the existing and proposed systems of trunk wires in the Yorkshire district, and also in the Lancashire and Cheshire districts, with which inter-communication is provided. The following are the principal trunk lines now in course of construction :—From York to Leeds *via* Tadcaster, from Sheffield to Buxton, from Sheffield to Chesterfield, and thence to Nottingham *via* Clay Cross, from Nottingham to Derby and Lichfield. This latter line will place the Nottingham district in direct communication with the Birmingham and Wolverhampton district. From Wolverhampton a line is in course of construction northwards to Stafford and Longton. By means of the existing lines from Longton to Hanley and a new line from Hanley to Buxton communication will eventually be effected between Birmingham and Manchester. The first telephone was placed in Yorkshire about the year 1879, and there are now in operation about 2,000 exchange and 350 private lines. The latest returns of the National Telephone system up to the 31st December last are as follows :—

Total number of exchanges		104
Total number of call offices		192
Number of exchange lines	7,301	
Number of private lines	1,177	
Total number of lines		8,478

Private House Lighting.—The "Old House," near Warwick, the residence of Mr. G. V. Fowler (of the firm of Fowler, Lancaster and Co., of Birmingham) has recently been fitted with electric light. Motive power is obtained from a Spiel's petroleum engine of 2 horse-power nom. Very good results have been obtained from this engine; it is found to require very little attention, and works economically. The dynamo is by Fowler, Lancaster and Co., and is shunt-wound for charging accumulators. The cells are of the E.P.S. type, the lamps are of 50 volts, and the total number in use is 54. Two of these at the entrance gates are of 50 candle-power, the remainder are of 8 and 16 candle-power. One 200 candle-power lamp has also been provided with the intention of lighting the tennis lawn during the summer evenings. White porcelain switch and fuse blocks are employed, and the fittings throughout are of a very tasteful character. Mr. Fowler reckons that, light for light, the total cost of lighting amounts to about double that previously expended for oil. Messrs. Edmundson and Co., of Dublin and Westminster, have recently completed an installation of electric light at Lord Brassey's residences at Normanhurst and Park-lane. In the latter case only the lamps and wires were supplied, the current being obtained from the Grosvenor Gallery Central Stations.

Telephonic Communication with Ships.—The following is the cutting enclosed in Mr. Unbehaun's letter on this subject (see our correspondence columns):—"The first practical use of the ocean telephone cables that have been laid from the Largs Bay jetty to seaward, for the use of the Messageries Maritimes and the Orient Steam Navigation Company's boats, was made on Monday by the M.M. steamer 'Yarra,' the first vessel of either line that has arrived since the means of communication were perfected. The work of laying the cables was completed on Friday, during a considerable portion of which Mr. Unbehaun, by whom our telephonic department is managed, was engaged on the launch 'Blue Bell' examining the fixtures and appliances of this new departure in telephony in the colony. The communication has been effected in this way. Two separate cables have been laid from the Largs Bay jetty to a buoy, specially fitted up for the purpose, and moored about one mile from the jetty. The cables terminate there, and an attachment consisting of a couple of conical copper tubes has been effected to each cable. The steamers generally anchor within a third of a mile from the site of this buoy, and each of the firms interested (Messrs. Harold Bros. and Messrs. Stilling and Co.) are provided with a portable set of telephones and a drum containing about 700 yards of insulated wire. One end of this wire has attached to it a ring which is slipped over the conical tube at the termination of the cable, and this effects the communication. The work of connecting the cables with the steamers is done by the Steam Launch Company, and the wire unrolls itself from the reel as the launch proceeds from the cable buoy to the steamer. Thus is completed the connection between the steamers, Largs jetty, and Messrs. Harrold's and Stilling's Port and City offices respectively, so that their agents on board the steamers can communicate direct from the boat to Adelaide or the Port as desired. On Monday, when the 'Yarra' anchored, Messrs. Harrold Brothers' cable was paid out to her, and the line was used for the first time from the ocean steamers; a preliminary experiment with it having been tried on Friday by Mr. A. F. Durand, of that firm's Port office from the 'Blue Bell,' anchored some 700 yards from the buoy, when it was found that Adelaide could be distinctly spoken with. On Monday it was stated that it worked exceedingly well, no difficulty whatever being experienced in speaking from town, a distance, owing to the way the wires are connected, of about twenty miles. The practicability of submarine telephony in this Colony, and thereby communicating rapidly, and at the same time distinctly, with the ocean steamers calling at our ports, has thus been demonstrated, and much of the delay and launch-travelling that has hitherto been necessitated by the lack of such means of intercourse will now be obviated."

Coastguard Stations and the Electric Telegraph.—The *Liverpool Journal of Commerce*, March 1, 1888, writes on this subject as follows:—"It is said by those who have paid particular attention to the state of preparedness in Great Britain on the outbreak of war that glaring faults or deficiencies are quickly discovered; and the consequence is that pluck has to stand in the place of science and equipments. There was never, perhaps, a Minister at the head of affairs who was more desirous to secure the peace of Europe than the Marquis of Salisbury; but if the Continental Powers should resort to hostilities, it will be found almost an impossibility for Her Majesty to keep her armed forces out of the fight. But should a war break out, there would be a protest from one end of the land to the other for the immediate connection of all the coastguard stations by telegraph wires with the nearest offices. There are fleets of merchant ships and a vast commerce to protect, and this cannot be reasonably done unless the coastguard officers have the means of communicating with vessels off the coast. Warnings will be found necessary if armed cruisers are to be avoided, but at present this duty cannot be performed. All around the United Kingdom there are coastguard stations perched on commanding positions; but if an officer in charge saw an enemy's ship he might have to send miles by road or along cliffs before a signal station could be reached, and in the meantime captures would be easy of accomplishment in the absence of Queen's vessels. The coastguard officers could be of immense service to the Admiralty and the shipping interests if a system of telegraphy was at their command. War would scarcely be declared before there would be an outcry in the press, Parliament and among the public at the apathy of the Government in not carrying out such a needed aid to the Royal Navy. Our labours in endeavouring to bring this most urgent matter to the attention of all concerned have not, however, been devoid of fruit. In the report of the Royal Commission on Irish Public Works, just issued, the commissioners speak favourably of the importance of telegraphic communication in fishing centres, and in recommending the utilisation of Tory Island in this respect they are sensible of the fact that a submarine cable could be made applicable to the general trade for signalling purposes. There is a feeling gaining currency that delay is dangerous in so far as coastguard stations are concerned. Lord Nelson, in the height of victory, is reported to have said, 'If I were to die this minute, want of frigates would be found stamped on my heart.' In his days those ships were the eyes of the fleet, and ever ready to give chase. A future British admiral, who may be harassed by false information and kept impeded by want of positive intelligence, may some day exclaim in imitation of Nelson:—'My ships are captured in detail by an enemy whose actions I know nothing about, and were I sinking this moment I should cry as the sea engulphed me, "Why did not the Queen's Government give coastguard officers electric communication with the Admiralty?"' We have said that the signalling of merchant ships would leave a profit on the capital expended. Underwriters, chambers of commerce, exchange rooms, and other establishments would buy the reports, independent of British and foreign newspapers. We ask, therefore, as an instalment, a coastguard telegraph system, and the lighthouses and light-vessels will follow as a matter of course."

ELECTRICAL APPLIANCES USED WITH TORPEDOES AND SUBMARINE MINES.

BY CAPTAIN C. A. M'EVOY.

Whatever may be the future status of torpedoes and submarine mines, and however much their importance may be the subject of doubt and discussion at the present time, no maritime power can afford to entirely ignore them and to trust alone to the older weapons in the operations of war. The low cost of a system of coast defence by means of submarine mines as compared with the cost of guns, fortifications, and ships, must secure their partial or complete adoption by all nations having a seaboard to defend.

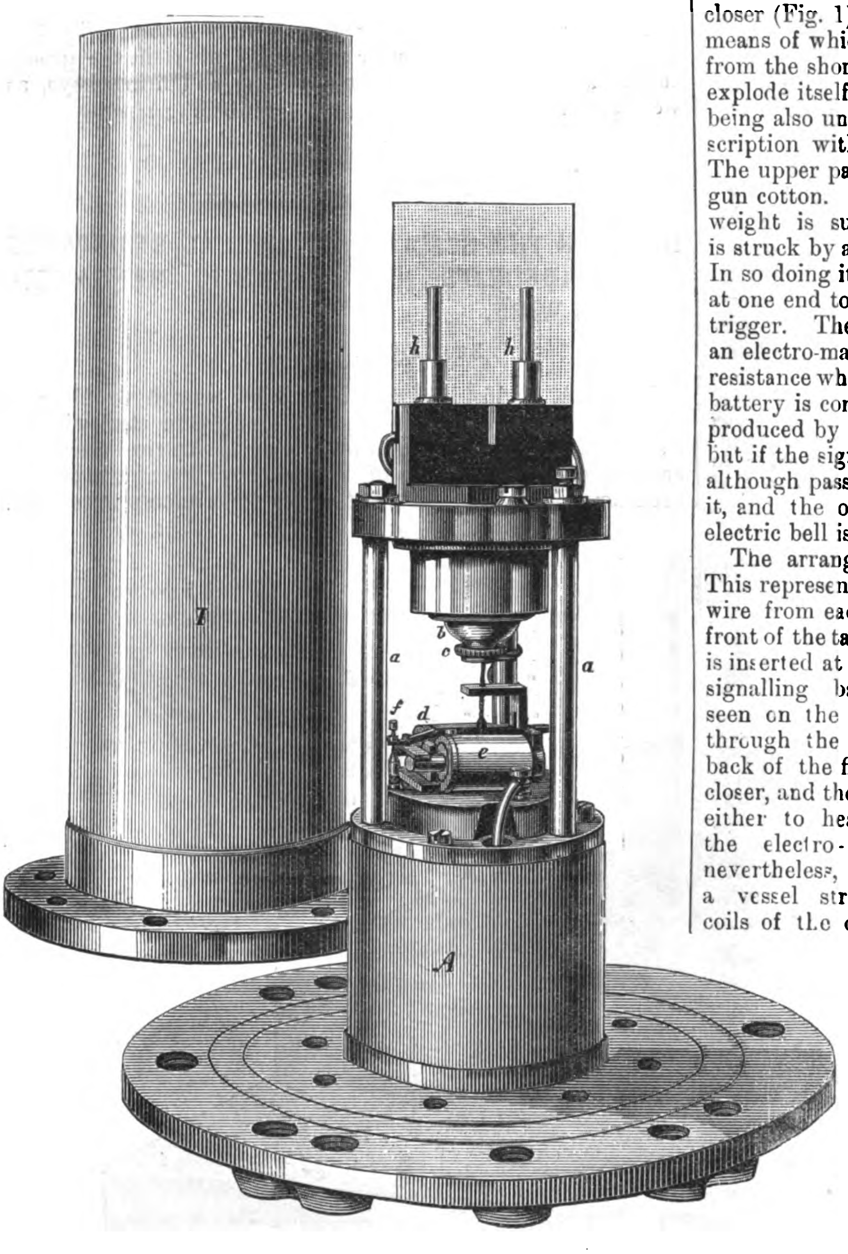

Fig. 1.—Circuit Closer. A. Base piece. a. Frame of circuit closer. b. Inertia weight. c. Adjustable screw for tension. d. Lever connected with armature of magnet. e Magnet. f. Armature contact. hh. Electric fuses. i. Envelope or cover for circuit closer.

The use of submarine mines will form no insignificant part of the means that will in the future be relied on for the defence of our rivers and harbours. The system to be employed will be mainly electrical, and so designed that while friendly vessels may pass over the mines in safety, they can, at will, be changed into a condition of danger to any vessel attempting to pass over them. The following is a description of some of the electrical submarine mining and torpedo stores supplied by Sir W. G. Armstrong, Mitchell and Co., Limited, Newcastle-on-Tyne:—

Electro-Contact Mines.—(Multiple-Main System.)

This system is one of the kind employed for the defence of rivers and harbours.

A group of four or more mines, each with sufficient buoyancy, is moored so that the mines will float a few feet below the surface of the water. All the mines in the group are connected to an iron junction box moored a few feet from the mines by means of short lengths of single-cored cable. A multiple-main cable carrying an insulated conductor to each mine connects the single-cored cables in the junction box with the shore.

Each mine is fitted with an electrical apparatus called a circuit closer (Fig. 1). The circuit closers contain an arrangement by means of which the fuses in the mines may be tested and fired from the shore, and by means of which each mine may also explode itself on being struck by a passing vessel, this action being also under control from the shore. A mine of this description with the outer case removed is shown in Fig. 1. The upper part contains the explosive charge, which is usually gun cotton. About the centre of the iron cylinder an inertia weight is suspended in such a way that when the case is struck by a passing vessel it swings to one side or the other. In so doing it pulls tight a string or chain which is attached at one end to the inertia weight, and at the other to a lever or trigger. The movement of this lever allows the armature of an electro-magnet to be attracted, and this closes a shunt of no resistance which cuts the magnet coil out of circuit. If the firing battery is connected at the shore end the increase of current produced by the fall of resistance immediately fires the mine, but if the signalling current only is on the circuit the current, although passing through the fuse, is not strong enough to fire it, and the only consequence is that a shutter falls and an electric bell is rung at the firing station.

The arrangement at the firing station is shown in Fig. 2. This represents a set of five testing and firing connections. The wire from each mine is brought to one of the terminals on the front of the table. In order to test its electrical condition a plug is inserted at this point which puts the mine in circuit with the signalling battery and the high-resistance galvanometer seen on the top of the case. The circuit is then completed through the galvanometer, through the magnet coils at the back of the firing shutters, the electro-magnet in the circuit closer, and the fuse itself; but the current is not strong enough either to heat the fuse or to pull down the armatures of the electro-magnets. The deflection obtained shows, nevertheless, that the mine is intact. When, however, a vessel strikes the mine and cuts out the magnet coils of the circuit closer as already explained, the current becomes strong enough to pull down the armature of the firing shutter. This causes the shutter to fall, and at the same time throws the bell into circuit. The shutter in falling cuts out its own magnet coils, and at the same time it closes a contact by which the current of the firing battery has to pass. The firing battery is, however, only in circuit when the plug seen on the right hand side is inserted. If this is already in place the mine is fired the moment the shutter falls. If it is not in place, and it is desired to fire the mine, on receiving this signal from the bell, the firing plug is now inserted. If it is desired to reset the mine without firing, it is only necessary to raise the shutter and withdraw the contact plug of the mine. The circuit being thus broken the armature of the electro-magnet in the circuit closer is restored to its original position by the retractile spring.

Double-Main System.

This system, like the multiple-main system, is employed for the defence of rivers and harbours, and differs from that system mainly in the economy of cable it secures. Instead of requiring a separate conductor to each mine, as in the multiple-

Digitized by Google

main system, the double-main system has but two conductors for testing and firing all the mines in a group.

The iron junction box contains an electrical step-by-step arrangement that works in unison with a similar instrument

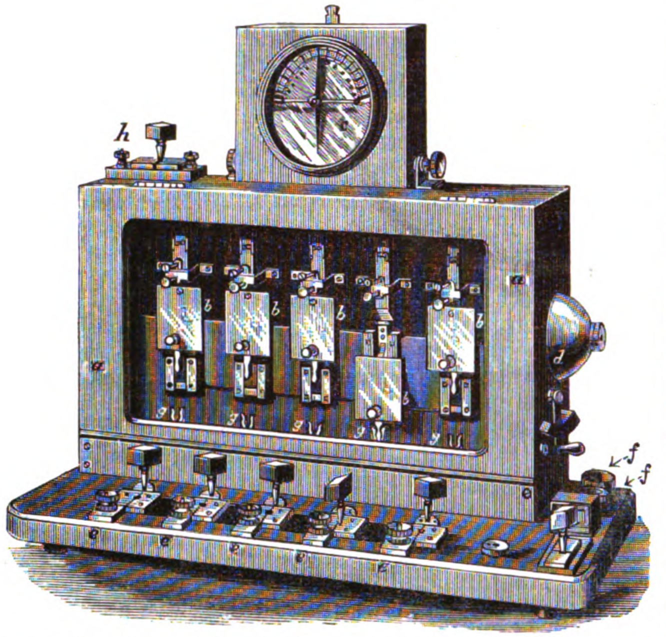

FIG 2.—Signalling or Shutter Apparatus. *aa.* Outer case of apparatus. *bbbb.* Shutters or falling signals. *c.* Galvanometer for testing mines. *d.* Bell for indicating fall of shutters. *eeee.* Mine connections. *ffff.* Battery connections. *gggg.* Spring contacts for switching in firing battery. *h.* Key for switching galvanometer in or out of circuit.

in the double-main system by a magnetic disconnector, a novel device that is free from the objections inherent in the ordinary disconnector—which consists merely of a fine platinum wire within the junction box, and is intended to be fused by the firing current. The difficulty of securing the fusing of the platinum wire disconnector at the instant the fuse in the mine is exploded is entirely obviated by the use of the magnetic disconnector. The junction box contains a set of electro-magnets, one for every mine with which it is connected. These magnets come into circuit successively as the step-by-step movement is actuated from the shore. The firing current pulls down the armature of the magnet coil then in circuit, and cuts out the coils themselves, as in the case already described. When the armature rises again it is caught by a tripping lever and held in a position in which the wires leading to the mine are entirely out of circuit.

The shore instrument in the double-main system (Fig. 3) is provided with a single shutter for all the mines in the group. It has also a bell, galvanometer, testing and firing keys, as well as the step-by-step movement described.

(To be continued.)

NOTE ON THE SPECIFIC ELECTRICAL RESISTANCE OF HADFIELD'S NON-MAGNETIC MANGANESE STEEL WIRE.

BY PROF. J. A. FLEMING.

Mr. R. A. Hadfield having been kind enough to place in my hands a sample of non-magnetic manganese steel wire for examination, a determination of its specific electrical resistance and coefficient of variation of resistance with temperature has been carefully made. The first set of experiments were made

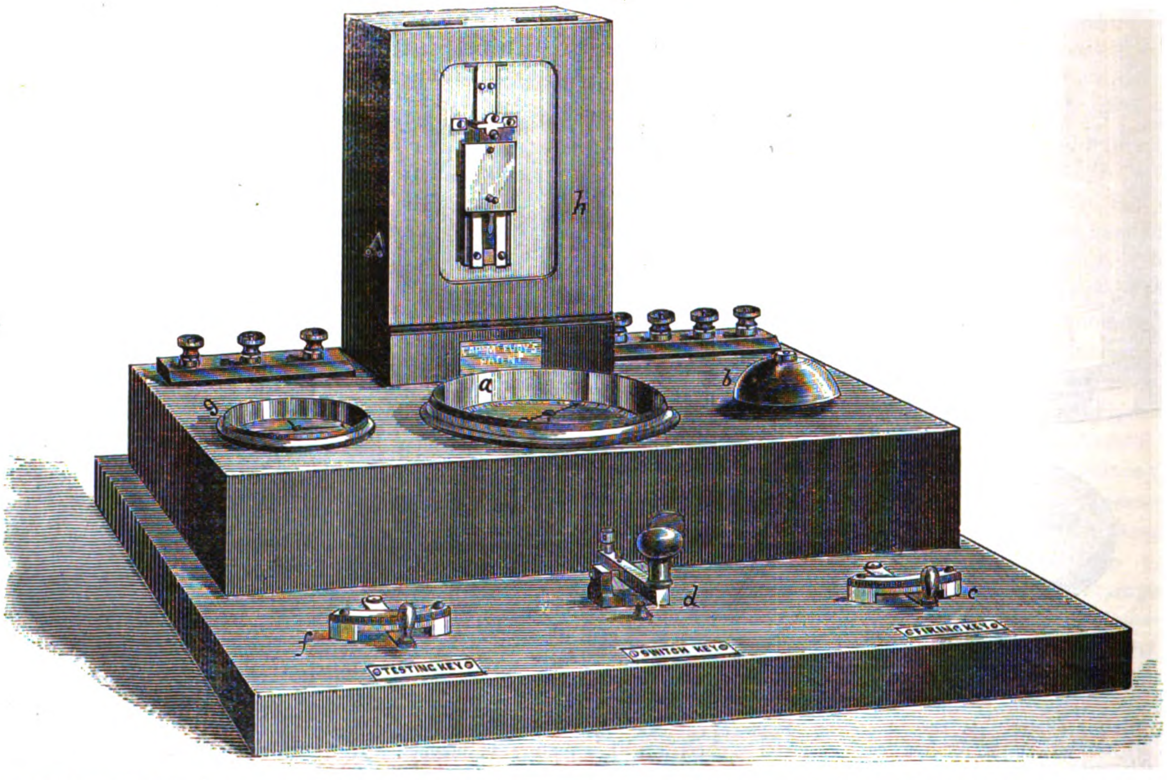

FIG. 3 shows the shore instrument for double-main system. *a.* Indicating disc with pointer, showing which mine is in circuit at the time. *b.* Bell *c.* Firing key. *d.* Switching key *f.* Testing key. *g.* Galvanometer. *h.* Shutter box.

on the shore, very much after the fashion of the old Breguet "A B C" telegraph. By means of these two instruments all the mines in a group may be separately tested and fired through the double-main cable.

When any one of the mines in a group is exploded it is necessary that it should be cut out of the circuit, or an "earth" would be established through the broken wire. This is done

by Mr. R. Berncastel, in the Physical Laboratory, University College, London.

A length of the manganese steel wire equal to 330·85 centims. was taken, and the mean diameter determined by gauging in several positions, and also checked by a determination of the specific gravity. The mean of several determinations gave ·086 centim. as the mean diameter of the wire.

Digitized by Google

The resistance was determined at several temperatures between 0°C. and 100° by heating the wire in an oil bath, with the following results :—

Temp.	Resistance in B. A. units.
2°·66 C.	4·045
13°·25 „	4·089
52°·60 „	4·284
94°·30 „	4·503

Plotting these resistances as ordinates to temperature as abscissæ, we find a nearly straight line. Expressing the resistance as a function of temperature in the form

$$r = a + b\,t + c\,t^2,$$

we find, as the values of these constants,

$$a = 4{\cdot}03362$$
$$b = {\cdot}004337$$
$$c = {\cdot}00000696.$$

and the resistance R_t at t°C. in terms of the resistance R_0 at 0°C. is

$$R_t = R_0\,(1 + {\cdot}001076\,t + {\cdot}00000173\,t^2).$$

Calculating back the resistances at the observed temperatures we have the following agreement between the observed and calculated resistances—

Temp.	Resistance calculated.	Resistance observed.	Diff.
2°·66	4·045	4·045	·000
13°·25	4·092	4·089	·003
52°·6	4·281	4·284	− ·003
94°·3	4·505	4·503	·002

The specific resistance at 2°·66 C. is then $\frac{4{\cdot}045 \times {\cdot}00567}{330{\cdot}85}$ = 69·3 microhms per cubic centimetre (B.A. units), or at 0°C. is 69·1 microhms per cubic centimetre, measurements being in B.A. units. Translating this into Legal or Congress ohms by multiplication by ·9889 we have for the specific resistance of this sample of manganese steel = 68·3 legal microhms per cubic centimetre.

The coefficient of variation of resistance with temperature from the above experiments is ·12 per cent. per degree centigrade.

A similar experiment was made for me by Mr. A. H. Bate, working independently on a portion of the same wire. A length of 28·25 inches of the wire was measured off. The mean diameter was taken in a very large number of places, and found to be ·0795 centim., the lesser diameter in this case being accounted for by the fact that the wire had been softened (by sudden cooling), stretched, and cleaned, in order to permit of a more careful determination of its mean diameter.

The mean area of cross section was ·004962 square centimetre. The resistance at 14° C. was 0·991735 legal ohm. Hence, the specific resistance at 14° C. is—

$$\frac{{\cdot}004962 \times {\cdot}991735}{28{\cdot}25 \times 2{\cdot}54} = 68{\cdot}6 \text{ legal microhms per cubic centimetre.}$$

The resistances of another length of the wire was taken at different temperatures and found to be as follows :—

Temperature.	Resistance. (Legal ohms.)
7°·07 C.	2·4103
7°·30 „	2·4105
35°·12 „	2·4929
33°·72 „	2·4869
58°·20 „	2·5630
54°·70 „	2·5515

The mean coefficient of variation of resistance with temperature from these observations is ·1224 per cent. per degree centigrade.

If we reduce the specific resistance at 14° C. to that at 0°, we find it to be 67·4 legal microhms per cubic centimetre. The mean of the results by the two observers is nearly 68 microhms per cubic centimetre.

As a means of comparison, we may place alongside of this number the average values for annealed copper and German silver—

	Specific resistance in Legal microhms per cubic centimetre at 0° C.
Annealed copper	1·624
German silver	20·9
Platinoid	32·8
Platinum silver	24·36
Manganese steel	68· (about)

Accordingly, Hadfield's non-magnetic manganese steel has a specific electrical resistance some three and a-quarter times that of German silver.

The coefficient of variation of resistance with temperature is about three times as great as that of German silver. For the sake of comparison we place alongside of it those of the following alloys. :—

Average percentage variation of electrical resistance per 1° C. between 0° C. and 100° C.

Platinoid	·021
Platinum-silver	·031
Gold-silver	·065
German silver	·044
Cast iron	·080
Manganese steel (Hadfield)	·122
Copper	·388

This sample of manganese steel was to all ordinary tests entirely non-magnetic, and was not in the least attracted by a powerful permanent steel magnet.

The great specific resistance of the wire would make it very useful in electrotechnics, if the working of the wire did not present great difficulty. The wire is exceedingly hard and can only be softened by heating to a bright red heat and cooling it suddenly. Slow cooling renders it hard again. If, however, the wire can be prepared in a soft state, then its high melting point and consequently great current-carrying capacity, combined with its high specific resistance, might make it a useful material to use for resistances on which to run dynamos in testing. Its specific resistance is about 6—7 times that of iron wire. It would not, however, be a good material for standard coils, on account (apart from the difficulty of working) of considerable variations in electrical resistance of different samples, and also on account of its relatively high coefficient of variation. It is certainly very remarkable to note the extraordinary change in electrical and magnetic properties produced in iron by the addition of 10—20 per cent. of manganese.

ALTERNATING CURRENT ELECTRIC MOTORS.*

BY DR. LOUIS DUNCAN.

The alternating system of electrical distribution, possessing as it does many advantages for distributing electrical energy over extended areas, possesses certain disadvantages, among others that of not, at present, allowing the use of electric motors for the distribution of power.

Our knowledge on the subject of alternating currents is largely due to the work of M. Joubert and Dr. John Hopkinson. The latter showed first that alternating dynamos could be coupled in parallel, and afterwards that one dynamo could be used to drive another as a motor. He brought forward experiments tried by Prof. Adams and himself, in which one dynamo had driven another, the latter doing mechanical work. Mr. Siemens at the same time, in 1885, described experiments where he had driven both alternating dynamos and ordinary series motors by alternating currents. Dr. Hopkinson's mathematical work assumes that the curve representing E.M.F. is a simple sine curve ; that is, that $E = E_0 \sin 2\pi \frac{t}{T}$. It is importan to notice, however, that his principal conclusions do not depend upon this assumption, but would be true if the E.M.F. were any periodic curve. Since that time nothing of importance has

* Read before the American Institute of Electrical Engineers, February 14, 1888.

Digitized by Google

appeared on the subject excepting two short papers—one by Mr. Kapp on "The Maximum Work Obtainable from a Given Source of E.M.F.;" the other by Mr. Blakesley on "Conditions of Maximum Efficiency in the Case of Transmission of Power by Alternating Electric Currents."

In all of the mathematical work done on this subject it has been assumed that the various E.M.F.'s may be represented by a sine curve, and that only simple electro-magnetic actions enter into the problem. I do not believe that these assumptions are true. Since Joubert's experiments made in 1881 it has been known that the curve of E.M.F. of a Siemens alternating dynamo, where the external circuit had no statical capacity, was very nearly a sine curve. With some of the machines used to-day, and under the much more complicated conditions of distribution, this is probably not even approximately true. Neither is it true that the statical actions of the different forms of wire upon each other in the transformers can be neglected. Messrs. Hutchinson and Wilkes and myself have lately experimented on this subject, and we have obtained the curves for the currents in the secondary and primary circuits under many conditions. These observed results do not agree with the results of calculation in the few cases that we have worked out. Until we have fully satisfied ourselves in this matter I will avoid any but the simplest mathematical work.

Alternating-current motors are not in successful use; let us try and find out the difficulties they present and attempt to suggest plans for overcoming them.

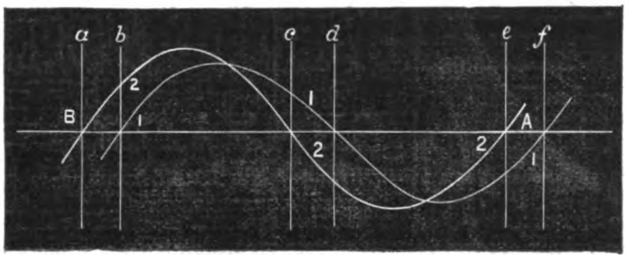

FIG. 1.

The energy being transformed at any moment in any dynamo-electric apparatus—in which I include dynamos, motors, transformers, &c.—is equal to the product of the current by the electromotive force produced by the apparatus. This is true for alternating as well as for direct-current apparatus. Generally we have:—

Work = E C. This is + for a dynamo – for a motor.

In alternating circuits E and C are constantly changing. If we represent them by curves, as before, we must multiply each value of C by the corresponding value of E, and if we add all these together from A to B (Fig. 1) we will have the work done by the current in one period. Now, if we consider values above the horizontal + and below it –, we have from *e* to *d* a + value of the product, from *c* to *d* a – value, from *c* to *b* a + value, from *b* to *a* –. The total work done then is [*e* to *d*] + [*c* to *b*] – [*d* to *c*] – [*b* to *a*].

Now we see that if we shift I I forward [towards B] or pull I back we have this work less, even though the curves themselves remain the same size. Now, this is one of the exceptions I take to the alternating system. In a direct system as the work decreases the current decreases, and the heating of the mains becomes proportionally less, since it varies as C^2; for example, if the maximum loss in the mains of a direct current plant were 10 per cent. of the average I imagine that the average loss is not over 3 per cent. In an alternating-current plant a decrease in the consumption of energy decreases the current very little; it simply shifts its position with respect to the E.M.F., and the heating, approximately equal to $\frac{C_0^2}{2}$ R, remains nearly constant. A maximum loss of 2·5 per cent. would probably mean an average loss of at least 2 per cent. This same remark applies to transformers and motors, and the average efficiency of the former will be considerably less than the maximum efficiency.

A distinction between continuous and alternating-current apparatus is this:—In continuous-current dynamos and motors the cores making up the windings of the armatures make different angles with the lines of force in the field, and the result, when the armature rotates, is a constant E.M.F., fluctuating but little; in alternating dynamos and motors the alternate coils are symmetrical with respect to the alternate poles, the remaining coils being symmetrical with respect to similar poles of opposite signs. The result is a varying E.M.F., changing as has been shown. In dynamos the effect of this is that the power applied either varies from zero to a maximum each period, or the armature changes its speed at different points and oscillates with a period equal to that of the E.M.F.

FIG. 2.

Let us now consider what takes place in the case of two motors, one continuous, the other alternating, one between mains where a constant continuous E.M.F. is maintained, the other where there is a constant alternating E M.F. In the first case representing current and E.M F. by curves, as we have been doing, we will have two straight lines, Fig. 2, one above the other below our horizontal axis, the former representing current, the latter the counter E.M.F. of the motor. Reckoning time along the axis we have for the energy transformed in the interval from *a* to *b* = – C E. As this is – it means that electrical is transformed into mechanical work.

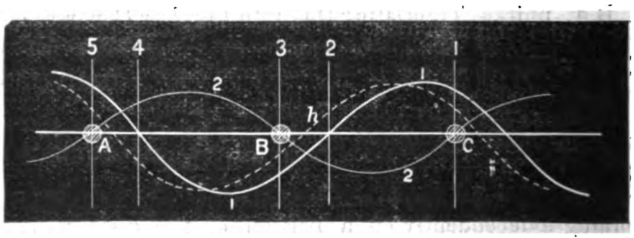

FIG. 3.

Now, let us consider an alternating-current motor built like an alternating dynamo, the field excited by a continuous current. If A B C (Fig. 3) are the poles of the field-magnets, supposed to be excited by a continuous current, then the curve I I will represent the counter or motor E.M F. If our motor is running slowly there will be two or three reversals of

FIG. 4.

current in the time it takes a coil to go from A to B (Fig. 4), and the product C E will be nearly zero, the positive and negative parts being almost equal. Whether it is + or – is somewhat a matter of chance, and if it is – from A to B it will very likely be + from B to C. Thus the armature is pushed first in one direction then in the opposite, and there is no definite tendency for it to rotate as a motor. This brings us to our first difficulty, a simple alternating-current motor will not start itself. Let us suppose, however, that it has been started by some means, and has reached such a speed that in the time of a reversal a coil shall have moved over the distance between two similar poles. We will have the state of things in Fig. 3 and

Digitized by Google

the armature will continue to rotate. Now the position of the curve I I is fixed, we will consider the position of I as determined by the position of the armature coils when the current in them is zero; for instance, if the speed increases a little the curve will advance as shown by the dotted line. The total work transformed is the product of the two curves; from 1 to 2 it is −, from 2 to 3 it is +, from 3 to 4 −, from 4 to 5 +. The result is − [1 to 2 + 3 to 4] + [2 to 3 + 4 to 5]; part of the time, then, the machine is working as a dynamo, part of the time as a motor; the difference of the values represented by the brackets gives the mechanical work that is really available. Now while the available work is the difference of these areas, the difference becoming small as the load is decreased, the heating is the *sum* C^2 R for all the values of the current, and is independent of the position of its curve, as has been pointed out above.

Looking at the figure again we see that from 1 to 2 the armature is pushed forward by the current in the line; from 2 to 3 it is pulled back, since it is acting as a dynamo feeding into the line, and can only get the energy to produce the current by decreasing its speed and drawing from its energy of motion. The armature oscillates then, and it is evident that the amount of its oscillation depends on the kind of work it is doing. If it is driving heavy wheels or machinery having considerable inertia, it will only have to slow down slightly when it becomes a dynamo. If it is lifting weights the amount of oscillation will be considerable.

It is evident that there is a certain position of the curve I that will make the available work a maximum. If the motor is doing all of its possible work the curve will take up this position. As the load is decreased the speed will increase for an instant until the curve has shifted forward into such a position that the sum of the products E C is equal to the work done. In fact, we can plot a curve representing

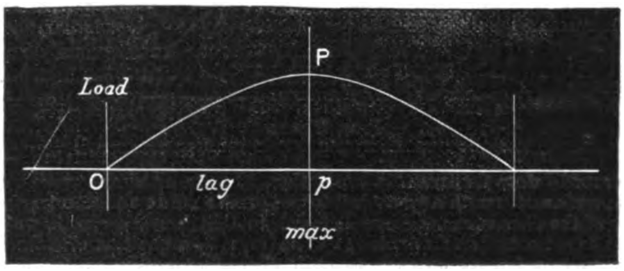

Fig. 5.

values of the distance from the point the current curve crosses the axis, to the same point when the work is zero, corresponding to different loads.

Now, the value of this lag, as we will call it, cannot be greater than O P (Fig. 5), for although we might extend our curve on the other side, yet a slight increase in our load will cause the armature to fall back, decreasing the available work, and suddenly stop. It is, in fact, in unstable equilibrium.

Suppose we have found the value of the lag that will give us a maximum value of the work, and have calculated this value by the ordinary mathematical methods employed, the real work we can obtain is less than this, for the current curve oscillates on both sides of the maximum, supposing we *could* work at the maximum—that is, it is only for a very short time in the best position; so that if we take the sum of the work for a period, it will be less than the calculated maximum. In reality we must work slightly in advance of the maximum, for if we were too near it the curve would fall behind P, and will then be in unstable equilibrium and stop. The practical maximum will then vary according to the amount of the oscillation—that is, according to the nature of the work being done.

It seems to me that the possible forms of alternating motors are:—(1) Ordinary series motor; (2) An alternating dynamo reversed, the field being excited by a continuous current; (3) An alternating dynamo reversed, the field being excited by the alternating current first corrected by a commutator on the shaft; (4) The arrangement suggested by Prof. Thomson, which is described below.

In the first type—a series motor—there is no difficulty in starting; the motor will start of itself. There are these troubles, however; the armature and field must both be thoroughly laminated to prevent eddy currents; the magnetism of such large masses of iron being rapidly reversed will cause losses unless both field and armature are far from saturation; that is, the mass must be great. Again, Mr. Kapp has shown that to obtain the maximum work we must have, approximately, the counter E.M.F. of the motor equal to the E.M.F. of self-induction—a condition almost impossible to realise in practice. The motor must be governed in some way, as it will not govern itself.

The alternating motor with a field fed from the alternating circuit, the current being commutated, will start itself. I do not know if this has been generally recognised. If, in Fig. 6, A and B are poles and C one of the armature coils, the effects of the currents will be as shown by the two sets of signs. The effect of either arrangement is to move the armature in the direction of the arrow. When C gets opposite A the commutator changes the relative directions of the currents in C and A, and C is repelled by A and the armature continues to rotate. The maximum work will, I think, be done when the speed is such that a reversal takes place in a distance A to B. The mathematical investigation is difficult, and until I am satisfied as to the assumptions usually made I will not attempt it. We have as an advantage of this type that it will start itself; a disadvantage is that the fields must be carefully laminated, there is loss in reversing them, and there will be for some speeds considerable sparking at the field commutator. I should not imagine, either, that the work obtainable from such a motor would be as great as if its field were fed by continuous currents.

The motor obtained by reversing an ordinary alternating dynamo has advantages and disadvantages. It perfectly regulates itself, and the field-magnets need not be lamented; that is it can be made cheaply. It will give a greater output from

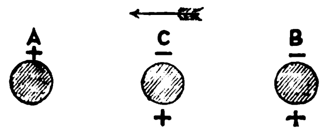

Fig. 6.

a given source of current than corresponding machines of either of the types already discussed. Its disadvantages are that it must be started independently. We must have a continuous current to excite the field, and if a load having any considerable inertia be suddenly applied the motor will stop. This last objection, by the way, will apply to the type of motor previously discussed, provided, as I have supposed, the maximum work is obtainable when the counter E.M.F. has the same period as the applied E.M.F.

Let us see what means we can employ to start the motor and excite the field. We could start by passing the commutated alternating current through the field, as in the second type of motor discussed, changing our connections when the proper speed is obtained, so that a continuous current from some external source passes through the field and the alternating current is shut off from it. Another way would be to have on the same shaft with our main motor a motor arrangement, such as was described by Prof. Elihu Thomson in his valuable paper on Alternating Current Phenomena, read before the institute. With this arrangement we can do more than start the motor. Prof. Thomson pointed out that when this auxiliary motor reached a certain speed it would produce a continuous current in the external circuit of its armature. This current could be used to excite the field of the main motor. By properly proportioning the number of coils in the main and auxiliary motors, this continuous current would be produced just when the motor had arrived at its proper speed, and it is evident that we can make this current operate an automatic device to make the circuit of the main motor at this moment. I should imagine, however, that a motor made in this way would be expensive and not particularly efficient.

Digitized by Google

What seems to me the simplest, cheapest and most efficient means of running alternating-current motors is this. Build the motor on the same general plan as the dynamo, with such modifications as the different conditions of working impose, and start it and excite the field-magnets from a continuous-current circuit, run with our alternating circuit, supplied with current by a dynamo at the central station. If we wish to distribute 500 horse-power our continuous circuit should have a maximum capacity of about 50 horse-power. To start the motor we should have the following arrangement:—There should be two breaks in our armature circuit, one between the regular brushes of the machine, the other at a commutator for the continuous current. At this second break the two ends of the circuit should be taken to alternate bars of the commutator, the number of bars being such that the direction of the current is reversed every time a coil passes a pole. The alternate bars are normally connected by a metal ring pressed against them by a spring. In this case we will have the normal circuit just as if there were no continuous-current commutator. On the motor would be a switch-board that would accomplish the following things:—If we wish to start we turn the handle of the switch to a certain position; this will short-circuit our regular brushes, and by the aid of a couple of levers will drop the continuous-circuit brushes on the commutator, at the same time pulling away our metal ring. The motor will then start as a continuous-current motor. When it has reached its proper number of revolutions, or is above it, turn the handle a little further; the continuous current brushes will be raised, the metal ring will connect the commutator bars, and the alternating circuit will be made and the motor will continue to run and will do work.

Now, I consider that the advantages of this plan are these:—It makes the motor simple and cheap to build; it will be more efficient and have a greater output than the other motors that have been discussed; the currents to excite the fields will have to be supplied anyhow, and they cannot be supplied more economically than from the central station; being simpler there will be less liability of derangement.

The motor described by Prof. Thomson that I mentioned above consists of field-magnets through which the alternating current flows, with an armature not in any way connected with the external source of current, but which has currents induced in it just as if it were the secondary of a transformer. The circuits of all of the armature coils are open excepting one that is in such a position that the current induced in it will be repelled by the pole-pieces. In this form I do not think the motor will be particularly efficient or give any considerable output. It is possible that the principle may be further developed to give a considerable output, but I do not believe that any motor in which the field is fed by alternating currents can be cheaply made, although this is a matter of which I have no experience.

To prevent motors stopping when the load is thrown on it would only be necessary to drive the load from a friction pulley on the shaft of the motor. The pulley should be so adjusted that it will turn just before the motor falls behind its point of its maximum work.

It is possible that all of the plans I have suggested have been tried by the different inventors who are at work on this subject. If a motor of each type that I have mentioned were built and proper experiments were tried upon them, we would —provided we had the ability to interpret and apply our results—have the data necessary to design the best possible machine of each type, and if we build these it should settle the question as to which form will be the best. There is no necessity in building an indefinite number of motors to experiment with. It is too much the custom, if we wish to design a dynamo for instance, to build twenty different ones and see which is best. One machine, with proper experiments and deductions, should put us on the right track.

Dr. Holmes once said that when he had written anything that pleased him it immediately seemed very old indeed. I, with humility, feel much the same way, as if what I had said this evening is so apparent that everyone must have known it. I can only hope that some of the suggestions I have made will help the development and final successful application of the alternating-current motor.

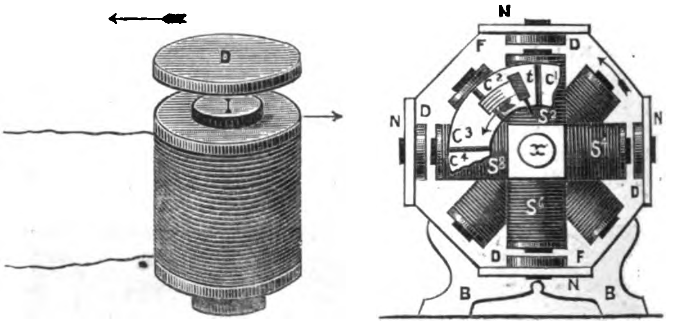
DISCUSSION.

Mr. CROCKER: There are two or three practical points that suggest themselves to me. In the first place, Dr. Duncan speaks about the great cost of a laminated field, and he speaks of it as if it were practically a bar to the use of laminated fields. If I were going to make a wrought-iron field, or if I were bidding for a contract to make wrought-iron fields, I would prefer to make them laminated rather than of forging or any other form of wrought iron that I have ever come across. So far as I am concerned, I prefer the laminations. I have been experimenting somewhat myself in this direction, and was quite pleased with that feature of the alternating current motors, viz., that they *did* involve laminated fields.

Lieut. F. J. PATTEN: Dr. Duncan has shown us that the curve of counter-electromotive force has a variable position with respect to the mean, *i.e.*, oscillating from side to side, and I wish to ask whether any such oscillation takes place or not provided the motor is running under a constant load.

Dr. DUNCAN: I think the oscillation certainly would take place no matter what load is on the motor, because in a part of every period—and a period takes place every one three-hundredth of a second—the motor is not a motor at all, it is a dynamo. That is, it is absolutely putting current into the main line. The only way to get the energy and throw that current into the main line is by decreasing its speed and drawing from its energy of rotation. Therefore, where it is in those areas it will slow down in speed. Where it is in the larger areas it will increase its speed; but the oscillation will occur whether the load is constant or not.

Lieut. PATTEN: I have designed a form and made some elementary tests of a motor of the kind suggested by Prof. Elihu Thomson in his



FIGS. 7 AND 8.

paper read before the Institute last spring. I have always regarded Prof. Thomson's motor with a great deal of admiration. It would seem from some of the discussions we have listened to that whatever work we are going to get out of an alternating system must be a question of difference between two factors opposed to each other—the self-induction of the circuit and the power generated as well as the heating. Inasmuch as all our results must be due to the difference between the two quantities, I have have worked upon that line, trying to give that difference its greatest possible chance to do some work. If you will remember, Prof. Thomson's motor, as Dr. Duncan has explained it to-night, consists in a fixed field and a revolving armature, the circuit of which was closed when it came into position of action; at that point the circuit is momentarily closed.

Fig. 7 illustrates this principle. S is a solenoid with a soft iron core, I and D a closed circuit of high-self inductive capacity, preferably a copper disc. When alternating currents are sent through the coils of the solenoid S, and the centre of the disc D is not immediately in the prolongation of the axis of the solenoid, there is a tendency to separate, as indicated by the two arrows. As in all forms of alternate-current dynamo-electric machinery the effective effort is always due to a difference between two unequal and opposing actions, so in any machine in which the principle thus described finds application the rotary torque or moment of rotation will be due only to a difference of two efforts, as shown in the preceding analysis, and the machine here illustrated is a simple mechanical arrangement of parts, the purpose of which is to cause this tangential effort, however small, to work at a possible maximum of advantage. Those who recall the forms of machine illustrated in a former lecture and based upon this principle will remember a form of machine not differing widely from the ordinary direct-current machine. The armature placed at the centre of the machine consisted of a number of coils of high self inductive capacity, the different circuits of which were closed in succession as they arrived in the position of maximum repulsive action. In the machine I have designed the application of the same principle is reversed, with the apparent effect of producing a more continuous rotary effort as well as a greatly increased moment of rotation by virtue of placing the point at which the effort is applied farther from the axis of rotation, and thereby giving to the force at work, however small, a much greater lever arm. Figs. 8 and 9 are end and side elevations of the machine, and Fig. 10 is a diagram of circuits and connections. A polygonal frame F F F is connected by lateral strips N N, and all is supported upon the base B B. Secured to the lateral strips N N are two sets of copper discs D D and *d d*. These discs constitute the armature of the machine; they are arranged peripherally, as shown, fixed to the frame structure, and con-

Digitized by Google

sist of circuits of high self-inductive capacity that remain permanently closed.

A spindle x x (Figs. 8 and 9) carries a revolving switch, C^1C^2, or sunflower, which is secured to the spindle and turns with it. This sunflower commutator constitutes one terminal of the machine, while an insulated ring b +, and its contact brush secured to the support P P, constitutes the other. Under each set of discs, D D and d d, and secured to the spindle x, is a set of solenoids, those of one set being placed at an angle of 45 degrees to those of the other set, from which it results that these two sets of solenoids will each come alternately into action with respect to its own set of copper discs. Each set of solenoids has its four coils connected in series and the two sets are arranged in two independent circuits. Both have one terminal secured to the contact b +, and the

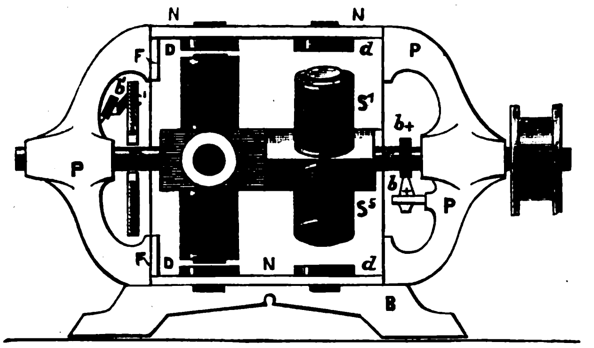


Fig. 9.

other terminal to the alternate segments of the revolving sunflower. This system of connections is shown in Fig. 10, in which the eight-part commutator is shown with alternate segments connected to each other in separate series. The coils S^1, S^3, S^5, S^7, form one set of revolving solenoids connected in series from the rubbing contact b +, which forms one terminal of the machine, to the commutator segment C^1, and thence to all the odd-numbered segments. In like manner the other set of solenoids S^2, S^4, S^6, S^8, are similarly connected in series to all the even-numbered segments, C^2, C^4, C^6, C^8. From this arrangement it results that, as the spindle revolved, carrying these solenoids as a sort of fly-wheel, the alternating current will be sent in rapid succession first through one set of solenoids and then through the other, and by suitably placing this commutator upon the spindle it can be made to send the current through the different sets of solenoids during the periods of maximum effort of repulsion between each set and its corresponding set of copper discs.

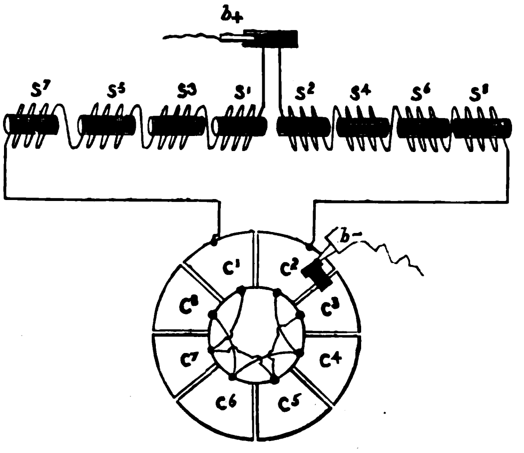

Fig. 10.

The moment of rotation is evidently a maximum under this system of construction, and by increasing the number of sets of solenoids that follow each other in action the effort of the rotary torque may be made nearly continuous and constant.

It is evidently not contemplated that this motor shall drive horse cars. Its efficiency is not high, and its form renders such an application quite impossible; but it can find a place in the smaller industries, where light motors fill a definite requirement, and render an alternate-current circuit a paying one during the working hours of the day.

Mexico and the Synchronising of Public Clocks.—The authorities of the city of Mexico are making arrangements to have one bell in each of the church towers of the city attached by means of electric wires to the clocks in the cathedral, so that the correct time may be given by each clock simultaneously every quarter of an hour.

"The Electrician" in America.

'THE ELECTRICIAN" *can be obtained in America from* D. VAN NOSTRAND, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

THE ELECTRICIANS' DIRECTORY.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY.

NOW READY.

Volume XIX. of "The Electrician," strongly bound in cloth, is NOW READY, price Ten Shillings and Sixpence.

Cases for binding "The Electrician," price Two Shillings, Now Ready.

PROSPECTS OF THE ELECTRIC LIGHT AMENDMENT BILL.

While making due allowance for the ease with which people believe what they wish to be true, there appear to be reasonable grounds for Lord THURLOW'S confident expectation that his Electric Light Amendment Bill will become law in the present session of Parliament. A more encouraging sign, perhaps, is to be seen in the fact that people who cannot be suspected of relishing the prediction have already resigned themselves to its early fulfilment. Foes as well as friends of the new illuminant are joining in the demand to give it a fair trial, and if the former still entertain a lingering hope that it may fail, they are wise in promoting a measure which will bring the issue to the test of practical experience without further prolonging their doubts and anxieties. Indeed, the Electric Light has latterly made such progress, in spite of legislation, that the gas interests may well be desirous of putting it under some legislative restrictions. It would never do to let the purveyors of the rival light discover that they could dispense with the regulations and limitations under which gas, to some extent, is supplied; and probably on this account, too, the gas light journals have found it expedient to say a good word for Lord THURLOW'S Bill. At all events, whatever may be the explanation, there seems to be no opposition to the measure outside of Parliament. Any latent objection on the part of local authorities has probably expended itself already; and its real meaning having been thoroughly exposed it is not likely, in any serious shape, to be revived.

In Parliament also the prospects are most encouraging. On the second reading of the Bill last Monday night in the House of Lords not a single voice was raised against it. The unanimity was very striking, not to say astonishing, noble lords responsible for the original Act becoming quite penitential when compelled to speak of its lamentable failure. Some excuses were offered by members of the Government of 1882 for the severity of the restrictions imposed on the infant industry, but they were not such as to redound to the credit either of men of business or of statesmen. The defence, in fact, amounts to this: we have in the past made bad bargains with the undertakers of gas and water supplies; therefore we will make a hard bargain with the undertakers of electric light. But there are

Digitized by Google

two people to every bargain; and as men of business the Government might have known that unless both parties were agreed to accept it there would be no bargain at all. And as statesmen, as well as men of business, they might have easily foreseen that any form of agreement which confessedly confiscated the property of one party to the other party would not only be rejected, but on grounds of public policy and morality ought to be rejected. However, the offenders have now—all except one, who has been doing more excellent service by way of reparation elsewhere—acknowledged their error, and what is still better, have promised to amend their ways. So far as can be gathered from what transpired on Monday night, the Bill will meet no formidable obstacle in Committee, and is pretty sure to pass the House of Lords.

As regards the Bill itself, it is fortunate in having Lord THURLOW as its promoter. In other circumstances the choice would not have been a happy one, as Lord THURLOW is chairman of one of the principal Electric Lighting Companies affected by this Bill. But it was extremely desirable that some one thoroughly acquainted with the working of the system, and who could speak authoritatively as to the effect of the Act of 1882, should have charge of its amendment. Moreover, and especially, it is to be noted that the Bill he has introduced is essentially an act of concession; it yields more than has been generally demanded—more, we think, for our part, than the Government have a right to claim; and this being so the fact that a leading body of electric lighting undertakers are prepared to accept the terms which their representative has embodied in a Bill will go far to ensure their acceptance. Nobody can say that he has asked too much in adhering to the forty-two years of life for the provisional order; and his offer to strike out of the Bill all reference to the purchase of the goodwill in order to disarm the opposition of the Board of Trade will in some quarters be thought a great deal too generous. The clause as it stands which repeals Section 27 of the original Act deals with this point as follows:—After a period of forty-two years, or after the expiration of every subsequent period of ten years, the local authority may require the undertakers to sell "upon terms of paying the then market value of the goodwill of the business and of all lands, buildings, works, materials and plant of such undertakers . . . such value in case of difference to be determined by arbitration: provided that the value of such goodwill, lands, buildings, works, materials and plant shall be deemed to be their fair market value at the time of that purchase, due regard being had to the nature and then condition of such buildings, &c., and to the state of repair thereof, and the suitability of the same to the purposes of the undertaking; and where a part only of the undertaking is purchased, to any loss occasioned by severance; but without any addition in respect of compulsory purchase." We have spoken of the Bill, even in its printed form, as a concession; and it will, we think, be admitted that if Lord THURLOW abandons, not merely the customary consideration in respect of compulsory purchase, but the goodwill as well, our description is far from being exaggerated.

But whatever the shape this clause may assume before leaving the Lords, the Bill, as a whole, will go down to the Commons distinctly as a measure of public relief, and will, we believe, be there treated as such. The public have now joined in demanding freedom to use what kind of light they please, and the question is no longer one of the extinction or encouragement of a particular industry. If the electric lighting undertakers had to fight this battle alone they would, it may be feared, obtain scant consideration at the hands of the House of Commons in its present temper. But they have enlisted powerful allies in winning for the electric light the suffrages of the people, or, to put it in language less political, have gained the goodwill of a powerful public opinion. Candles and oil are under no proscription, and from the point of view of social convenience there is no conceivable reason for keeping electric light under a ban. Such of the public as want the light have a right to use it, and the Legislature cannot any longer hinder it either in the interests of the gas corporations or in obedience to socialistic doctrines of confiscation. This being the situation, the Electric Light Amendment Bill, although backed by the head of a powerful electric lighting corporation, will go down to the House of Commons not as a suppliant for favour but as a messenger of peace. If the terms which Lord THURLOW has expressed his willingness to accept find their way to the Lower House and become the law of the land, we can only hope that his sanguine expectations may be gratified. Forty-two years is not a long life for a new enterprise of this kind when we remember that it took twenty-five years to enable the gas industry to work at a profit. The probabilities are against the House of Commons rejecting so liberal an offer, and the unwonted forwardness of business in the House affords additional encouragement to the belief that the abortion of 1882 will be converted into a working Act of Parliament during the present session.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

CHAPTER VIII.—*The Calibration of Current Indicators.*

(Continued from page 439.)

86. The resistance-box is very simply manipulated for altering the amount of resistance in circuit. A vulcanite-

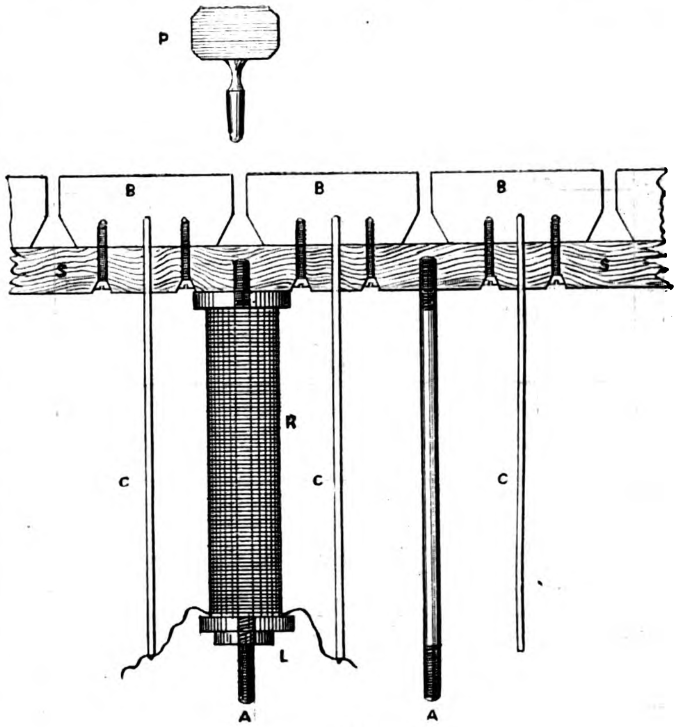

FIG. 51.

headed brass plug P (Fig. 51), when inserted into a round hole between two adjacent brass blocks, B B, short-circuits, or metallically bridges across, the resistance coil R, whose ends are connected to those two blocks. A number of coils wound accurately to different fixed resistances at the temperature *supposed* to be

Digitized by Google

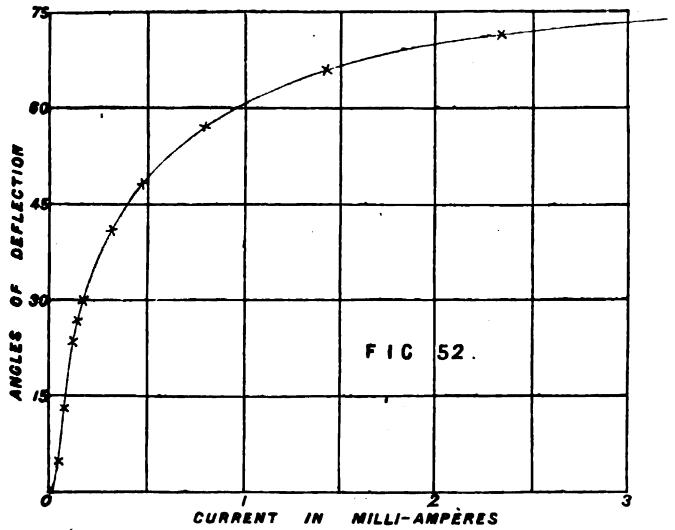
generally prevalent in this climate, viz., 60° F., are contained in the wooden box, the bobbins of the coils being fixed on the under surface of the ebonite slab S S, which forms the lid of the box. These wooden bobbins when wound are slipped over the brass rods A A, which are screw-threaded at each end, serving to screw them into the ebonite slab at one end, and to have a brass lock nut, L, screwed on at the other end after the bobbin is slipped on. The copper wires C C are soldered to their respective brass blocks, and it is to these wires that the ends of the coils are soldered, the final adjustment of the resistance of a coil being made at one of these joints. There are two of these wires to each brass block, so that each coil is attached to its own individual pair of copper wires, and the resistance of each coil can be finally adjusted separately. The wound coils (generally of German silver) are well baked and steeped in hot paraffin wax, melted to above the boiling point, before final adjustment. After this is accomplished the coils are steeped in the same wax, but this time only sufficiently warm to quickly coat them. The resistance of each coil is marked immediately above it on the upper surface of the ebonite slab, and the total resistance introduced into a circuit by means of the box is found by adding together all the marked numbers opposite holes where plugs have been removed. Sixteen coils are generally fitted to a resistance box, which is intended to read up to 10,000 ohms, the resistances of the sixteen coils being of such values that any number of ohms from one to 10,000 can be introduced in the circuit by arranging the plugs.

87. The astatic indicator shown in the figure measured 545 ohms, and gave a deflection of 75° when a resistance of 405 ohms was unplugged in the box, two cells, coupled together *in series*, being employed, each with an E.M.F. of 1·8 volt. With this deflection the current was therefore

$$\frac{(1{\cdot}8 \times 2)\text{ volts}}{(545+405)\text{ ohms}} = \frac{3{\cdot}6}{950} = {\cdot}0038 \text{ ampere}$$

or 3·8 milliamperes.

The deflections were then diminished by increasing the resistance in the box—that is, by unplugging more coils, and



the corresponding deflections for each change of resistance were noted. For facility of calculation afterwards it is advisable to make the unplugged resistances in the box such that when added to the resistance of the indicator a multiple of ten is always obtained. For example an even resistance of 2,000 ohms in the circuit is obtained when 2,000 – 545 = 1,455 ohms is unplugged in the box, and so on. Some eleven or twelve readings were taken in this way, which are shown plotted as a curve in Fig. 52, the currents being calculated as above in milliamperes. If the only cells available were of small plate surface, and therefore high resistance, and could not conveniently be connected together in parallel arc to reduce their resistance, as might be the case with a battery of a number of cells contained in a trough, the resistance of the battery used would have to be added to the other resistances in the circuit in the calculation of the current. One or two ready methods of measuring the resistance of a battery will be considered in a later chapter.

While taking the above calibration test there is no advantage in having a "key" in the circuit, by means of which the latter can be "made" and "broken," since if the circuit is broken after each reading, the needle of the instrument is set swinging inconveniently. The circuit should be permanently connected as in Fig. 50; and it should be observed whether each deflection of the needle remains steady, since if the deflection falls slightly it shows that the battery is polarising, and the readings consequently valueless, because the E.M.F. of the battery is slowly diminishing. This will not be at all likely to occur, however, as the resistance of the instrument is high, and we are adding resistances to it each time a reading is taken. To be sure, however, that no polarisation has occurred, the first reading is repeated, after the whole set have been taken, and if this is precisely the same as at first, it proves that the E.M.F. of the battery has kept constant during the test.

88. With each change in the resistance unplugged in the box the needle will be set swinging slightly, and instead of losing time in waiting for it to come to rest, its oscillations may be checked by a small magnet held in the hand. When the needle swings towards the magnet the latter should present the same pole towards the needle, repulsion between the two like poles checking the swing of the latter. The hand holding the magnet must then be taken right away from the instrument, when the needle swings the other way unless the operator is quick enough to present the other pole of the magnet to the needle on its receding swing. With practice the oscillations can be checked almost immediately in this way, but care must be taken that once the needle is brought to a standstill the little magnet is placed on the table at arm's length away so as not to affect the steady deflections. With even light needles a swing of a very small angle will last a tediously long time, owing to the long fine silk fibre suspension and the inertia of the moving needle, and a lot of time is saved by a little dexterity in checking the swings in the above manner.

(To be continued.)

THE NATIONAL ELECTRIC LIGHT ASSOCIATION OF AMERICA.

CONVENTION AT PITTSBURG.

The meeting of this Association, which was opened at Pittsburg on Tuesday, February 21st, is the seventh occasion on which this important body has been convened. The previous meeting was held in Boston in August last. The following is a brief synopsis of the proceedings at Pittsburg, together with a list of the papers which were read and discussed. Some of these we hope to produce later.

The convention was opened at noon on Tuesday by President J. F. Morrison, who read an able and impressive address on the growth of the association and of the electric lighting industry. He estimated the present figures of electric lighting at 3,000 incandescent and arc isolated plants, and 1,000 central stations, in which were installed or contracted for 175,000 arc lights and 1,750,000 incandescents, being, it was significant to note, in the proportion of 10 to 1. The association had 168 members and $971 in the treasury, with debts of only $98. Mr. Morrison also drew attention to the difference in the growth here and abroad, and said the whole explanation was to be found in vicious legislation.

Major W. C. Moreland, representing the city, then read an address of welcome.

Invitations were extended to the association by the Engineers' Society of Western Pennsylvania to attend its meeting on Tuesday evening. Invitations were also extended from the Westinghouse Machine Works and the Allegheny County Light Company.

Digitized by Google

The reports of the secretary and treasurer, summarised in the President's address, were read, and the various sub-committees were appointed.

The following papers were then read :—

"On Electric Light Cables," by Prof. ELIHU THOMSON.

"How can we Protect our Watches against the Influences of Magnetism ?" by Dr. LANGE.

On Wednesday Mr. Arthur Stuart, of the Legal Committee, presented a report with regard to the work on patent legislation done by the committee. After a discussion it was voted to continue the committee, with the proviso that there should be no expense to the Association. A resolution, raising the annual subscription to $20, was carried. The following papers were then read :—

"On Belting," by Mr. C. A. SCHIEREN.

"On Electric Motors," by Dr. LIEBIG.

"On Independent Engines for Incandescent Lighting," by Mr. W. LEE CHURCH.

"On Pressure Records," by Mr. J. B. EDSON.

"On the Relation of Electric Lighting to Insurance," by Mr. S. E. BARTON.

"On Electric Light Carbons," by Mr. W. G. PARKER.

On Thursday Mr. T. C. Smith invited members to see a "lighting-up" from the natural gas stand-pipes of the Philadelphia Company.

The following papers were read :—

"On the Distribution of Electricity by Alternating Currents," by Mr. T. C. SMITH.

"On the Energy of Alternating Currents," by Mr. O. B. SHALLENGER.

"On the Undergrounding of Electric Arc Light Wires," by Mr. W. W. LEGGETT.

After the reading of the papers the President called on Prof. George Forbes to address the meeting. The proceedings concluded with the usual vote of thanks.

ARC LIGHT CARBONS.*

BY G. W. PARKER.

From the standpoint of the manufacturer all well-baked carbons that are straight, free from cracks, and other similar defects, and made from pure material, are good carbons.

The electric light engineer will say that no carbon is good unless it will centre properly and give him a reasonably long life with a good light. He is not at all inquisitive as to the method of their manufacture, provided they give such results.

But as the manufacturer can go no further than to correct any errors in his mechanical processes, the value of the carbon afterwards depends upon the conditions of its use. Such carbons as are described in the first paragraph will with some currents be satisfactory, both as to light and life. In others, the light may be brilliant and the life too short, or there may be arcs too short or too long, flaming or other defects arising from the unsuitability of the carbon to the current, there being no inherent defect in the pencil itself. Therefore, to cover the whole ground of this important inquiry, we should also have the carefully-compiled statements of your experience of the behaviour of carbons burning in your lamps under varying circumstances. From this results of great value to both sides might be obtained.

There appears to be no trouble in determining what constitutes a good carbon mechanically, but to you a good carbon means one that will give you satisfactory results in your use of it ; and there we find several difficulties, without taking into account imperfections in your apparatus. The first is the difference in the strength of the current used in the different systems, and also in many cases in different plants of the same system, the corresponding differences in the resistance of each lamp, and frequently unequal adjustments of lamps in the same plant.

For convenience we are in the habit of referring to those systems in which a small current and a long arc are used as high-tension systems, and those in which a large current and short arc are used as low-tension systems. The requirements of the low tension seem to be a carbon that is hard, well plated, and a good conductor, the latter being the most important. In the high tension, on the contrary, hardness and conductivity seem to be of secondary importance. There is a tendency to flame and burn unsteadily when a hard carbon is used in these systems, and a softer one sometimes becomes necessary, which in many cases shortens the time in which a lamp will burn without being re-trimmed, but in such cases the difference is fully made up in the brilliancy of the light. On the other hand, where a soft carbon is burned in a low tension current, the tendency is to form needle points, which prevent the carbon from centering properly, cause them to heat and is apt to burn the holder.

Let us pursue the inquiry touching the questions of size, conductivity, mortality, and light, and ascertain if definite relations can be established in regard to them that may result in guiding us to the selection of perfect carbons for use from a mass of mechanically good carbons.

Diameters.—It is a matter of great interest to know in what manner and to what extent the size of the carbon affects the result in a current of given strength, covering, of course, in the general question of conductivity, the all-important results of light and life.

Hardness or Conductivity.—It is well known that a hard carbon offers less resistance to the current, or, in other words, has greater conductivity than a soft one ; therefore, in carbons of the same length and diameter, made of the same material, by the same process, conductivity increases and diminishes respectively with their hardness and softness. In either hard or soft carbons, whatever conductivity they possess respectively will be increased or diminished as their diameters is increased or diminished, the length being maintained. It would appear, therefore, that it is possible to make a softer carbon of a larger diameter that will be the equivalent, in conductivity, of a harder carbon of smaller diameter.

Mortality of Carbons.—Of carbons of the same hardness and length, but having different diameters, the larger will undoubtedly outlive the smaller. Of carbons of the same diameter and length, but differing in hardness, the harder will outlive the softer. Therefore a carbon of larger diameter which is soft may be equivalent to a smaller carbon which is hard, as to life, just as it has been shown to be equivalent in conductivity. The life of a carbon is of course dependent upon many vicissitudes, such as high winds, broken globes, &c. ; but under the same conditions the statement made above is undoubtedly a fact.

Brilliancy of Light.—It is well known and admitted that as between hard and soft carbons of the same diameter the latter will give a more brilliant light. It is just as well known that in case of hard carbons those of smaller diameter will within certain limits give a more brilliant light than those of a larger diameter. On the above statement of facts it may be regarded as settled, then, that with the same diameter, but differing in hardness, the hard carbon will possess greater conductivity and have a longer life, but with less brilliancy of light ; while the softer carbon will have less conductivity and a shorter life, with a more brilliant light. And further, that with uniform hardness, but differing in diameter, the larger diameter will have the greater conductivity and longer life, with a less brilliant light, while the smaller diameter will have less conductivity and a shorter life, with a more brilliant light.

The foregoing statements indicate invariably that with greater conductivity light diminishes and life increases ; and, conversely, that with diminished conductivity the brilliancy of the light is increased and the life shortened. In corroboration of this it appears that a small, hard carbon is practically the equivalent of a larger, soft carbon, their conductivity being also equivalent.

Heretofore, it has been considered probable that the diameter, candle-power, resistance per lamp, conductivity of the carbon point and strength of current are all interdependent, and a change in any of them will affect all the others, requiring a counteracting change or adjustment in some of them in order to restore the proper relations between them. This, if so, you can readily see is difficult to do, for part of the work is to be done by the manufacturer and the remainder is under your control.

On the other hand, if the deduction can be properly made from the statements herein presented, that the resistance of the carbon point will determine its capability in respect to light and life in the different currents, the trouble is practically removed. It is not impossible, I think, to construct a machine that will, at no great increase of cost, assort the carbons into groups of uniform resistance or conductivity. Then, with constant currents, clean lamps, perfect connections and insulation, you will ascertain practically that carbons mechanically good will prove to be good and uniformly so in actual service.

Much more could be written upon this interesting question, but this paper is already too long. I have noted for your discussion some important points which I hope your experience will enable you to determine definitely if they are well taken or not. I would be glad to have the whole question of the imperfect burning of carbon points thoroughly canvassed, so that manufacturers would get some hints as to what may be done by them in the way of correction when the fault lies at their door. It is especially desirable to be informed if that very disagreeable feature in the burning of carbons called "flaming" is always the effect of one particular cause, and what that cause is.

* Read at Pittsburgh, Feb. 22, 1888.

REVIEWS.

Munro and Jamieson's Pocket Book of Electrical Rules and Tables. Fifth edition. (London: Charles Griffin and Co.)

We gladly welcome the fifth edition of this indispensable little book, which is by this time far too well known to electricians to need any recommendation from us. The present edition has been further revised, and has received some important additions. The section relating to secondary batteries is now very complete, and we hope that in the next edition some space will be given to transformers, a subject which is at present altogether omitted.

Journal of the Society of Telegraph-Engineers and Electricians. No. 70. (London: E. and F. N. Spon.)

The present issue of the *Journal* is of special interest, as it contains the inaugural address of Mr. Edward Graves on assuming the presidential chair. This is followed by Mr. A. C. Cockburn's paper "On Safety Fuses for Electric Light Circuits, and the Behaviour of the various Metals usually Employed in their Construction." An important discussion followed the reading of the paper, which is here fully reported. At the same meeting Mr. A. Paris's Hydrophone was exhibited and described by Mr. W. H. Burns. The rest of the *Journal* is taken up, as usual, by abstracts and translations, chiefly from the French and German technical press, and we need scarcely add that these are also, as usual, well selected and well edited.

LONG-DISTANCE TELEPHONY.—THE INFLUENCE OF SELF-INDUCTION.*

As the author says at the end of his article, the formulæ with which it abounds are not very simple, and it will be impossible within the limits of an abstract to do more than glance at some of the conclusions drawn from the mathematical reasoning.

The three points raised are—

1st. What is the greatest distance over which conversation can be carried on for a certain kind of line?

2nd. What effect have submarine or subterranean sections on the air-line?

3rd. What sized wire should be adopted?

Preece has shown that the greatest distance at which speech is audible is equal to the square root of the fraction whose numerator is a constant depending on the nature of the line, and whose denominator is the product of the capacity and resistance. This formula takes no account of two very important factors, viz., the insulation of the line and its self-induction. Both these factors are duly taken into account in the author's calculations. He expected that the self-induction would have the effect of reducing the current, and thereby of weakening the sounds transmitted. He was therefore very much surprised, on applying his formulæ to the case of a copper air-line some hundreds of kilometres long, to find that the injurious effect of the electrostatic capacity, far from being increased by the self-induction, was in a great measure counteracted, and that the transmission was improved.

To show clearly the important part taken by self-induction, and how inexact is any rule for finding the limit of hearing from the product of the capacity by the resistance, the author gives the following results to which the theory leads:—

The self-induction has the effect of considerably increasing the current on arrival above the value which it ought to have according to Sir W. Thomson's theory.†

In those cases where Thomson's theory shows very unequal weakenings of sounds of different pitch, and consequently considerable alteration in the tone of a complex sound, the self-induction largely prevents this change, and alters completely the character of the transmission.

If the ratio of the self-induction to the resistance—which depends on the nature of the line, and not on its length—goes beyond a certain limit which seems to be reached for copper wires of 4·5 mm. diameter, the tone is not sensibly affected, even when the line is very long. Supposing the self-induction nil, it would be found, on the contrary, that the line deadens the sharp sounds and only transmits the low notes.

Taking as a special case a line of 1,200 to 1,500 kilometres, consisting of two copper wires 4·5 mm. in diameter, fixed about 1½ metres apart, it is found that the strength of the current on its arrival is greater than it would be on a local circuit of the same resistance, but having neither capacity nor self-induction.

A condenser or an electro-magnet inserted singly in a circuit will diminish the current; but if both are inserted in series in the same circuit they correct the reciprocal injurious effects—at least partially.

The greater the self-induction, the more, supposing the E.M.F. equal, the electric undulations will be reduced, but the more regular will be their propagation. If the self-induction is large—or, rather, if the ratio of self-induction divided by resistance to the time of vibration is large—the speed of propagation will be sensibly uniform, and the alteration of the undulations will be small in spite of the resistance. From this point of view, therefore, it is desirable to increase the self-induction or to diminish the resistance.

The effect of leakage on the line is to add to the injurious effect of the factor capacity multiplied by resistance another term, viz., the self-induction divided by the insulation resistance; and to introduce an entirely new term depending on the resistance of the line, the insulation, and difference of potential between two points of the line.

The current arriving at either station is so much the weaker, other things being equal, the nearer the leakage is to the centre of the line. An underground or submarine section on the line is more injurious when it is near the middle of the line than when its position is towards either of the two ends.

* From the Abstracts in the *Journal* of the Society of Telegraph-Engineers and Electricians, No. 70. Abstract from a paper by M. Vaschy, *La Lumière Electrique*, Vol. XXV., No. 27, pp. 18–22; No. 30, pp. 165–70; No. 32, pp. 264–70, 1887.

† For "Sir William Thomson's theory," we take it that we should read "Sir William Thomson's formulæ" for the speed of signalling on submarine cables.—Ed. *E.*

M. JABLOCHKOFF'S TRANSFORMERS.

It is not generally known—at least, it has only recently come to our own knowledge—that M. Jablochkoff had the idea of using a

Fig. 1

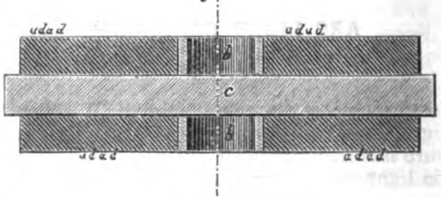

Fig. 2

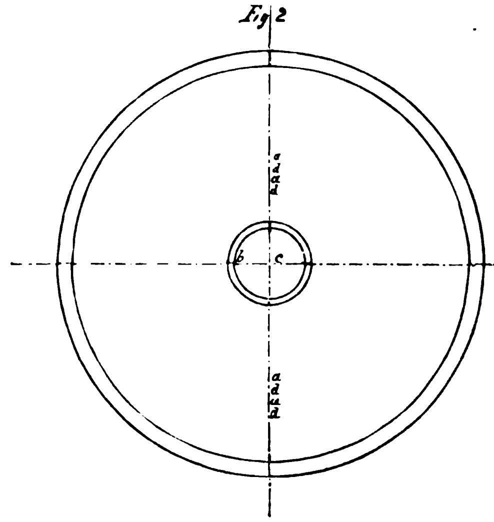


closed magnetic circuit transformer with alternating currents as long ago as 1877. In a patent of that year, describing a method of distribution primarily for use with Jablochkoff lamps, but available also for other purposes, the following passage occurs:—

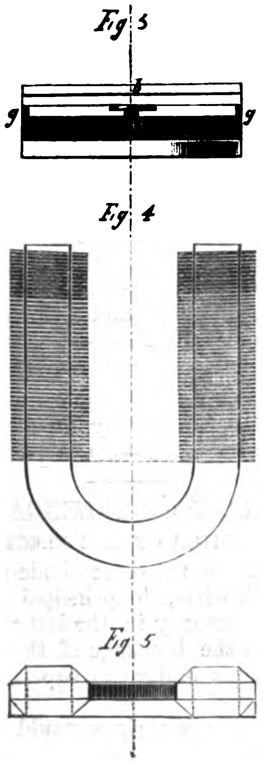
"In cases where continuous electric currents are employed the induction coils are provided with interruptors and condensers, either one to each or one to a number of coils. In the case of alternating currents the interruptors and condensers are dispensed with, the coils employed being constructed similar to the form of electro-magnets for which prior letters patent, No. 836, of 1876 have been granted to me."

Digitized by Google

The following is an extract from the specification alluded to :—

"Fig. 1 is a vertical section and Fig. 2 a plan of a disc electro-magnet according to my invention. A barrel or strip, *a*, of copper or other suitable conducting metal, along with a strip, *d*, of paper, cardboard, or other non-conducting material, is wound spirally round a core, *b*, of wood or other non-conducting material, so that the edge of the conducting band or strip rests against the face of the disc *c*, each convolution of *a* being separated from the next by the non-conducting band *d*, which is wound along with it. A similar arrangement may be applied to the opposite side of the disc *c*, as shown in Fig. 1. As an electro-magnet is thus produced, having one pole at the centre of the disc and the other at the circumference, *I complete the magnetic circuit*, and apply an armature in the manner shown in Fig. 3, which represents a section of a disc magnet, having the coil on one side. A central stud, *f*, and an outer ring, *g*, form respectively polar extensions to which an armature, *h*, can be applied. The disc, instead of being circular, might be of square or polygonal form, the coil being wound on a core, *b*, of suitable form ; also the surface of the disc might be concave or convex, and the metal coil might be wound without making absolute contact with the surface of the disc.

"Fig. 4 is an elevation of a horseshoe magnet, coiled with a helical band or strip. When the iron horseshoe core is of rectangular section, as shown in the plan Fig. 5, the strip can be wound round it by folding it over at the angles."



The remarkable thing in this description is the use in the year 1876 of the phrase "I complete the magnetic circuit," especially in connection with the subsequent statement that this type of magnet is applicable for alternate-current transformers. We have, however, been unable to discover that M. Jablochkoff ever actually constructed such a transformer as is here described. We have, in fact, some reason to believe the contrary.

It will be remembered that the Jablochkoff patents have been acquired by the United Electrical Engineering Company, Limited.

CORRESPONDENCE.

THE WEST INDIA CABLES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : Your New York correspondent, in his letter published in your issue of March 2nd, is hardly fair to the West India and Panama Telegraph Company.

It is well known on this side that the company has struggled heroically for many years past to maintain telegraphic communication with and between the West India Islands under most serious disadvantages.

No dividend whatever has been paid upon the ordinary shares for a number of years, and nearly all the earnings have been devoted to the maintenance of the lines. The subsidies received are quite inadequate, and, notwithstanding frequent and energetic representations, the Imperial Government, I believe, give no subsidy whatever.

On the Board are some of the most experienced cable and telegraphic authorities in the world. It is only necessary to mention such names as those of Sir James Anderson, Mr. C. W. Earle, Mr. H. Weaver, and Mr. W. Andrews, to show that the management of the company is in thoroughly competent hands.

Of course, the remarks in question may be meant as a reflection upon the British Government for neglecting to support lines which are of such importance to the Colonies and the mother country ; and if so those criticisms do not apply.

Considering the very insignificant part the United States have played in cable-laying, and the fact that practically submarine telegraphy is the result of the private enterprise of this country and the energy and foresight of such men as Sir John Pender, it is rather amusing to be told that "if the United States owned the West Indies the cable service would be a great deal better than it is."—Yours, &c.,

London, March 5th, 1888. G. N. R.

EFFICIENCY OF INCANDESCENT LAMPS; AND ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : In the very interesting and complete report on page 454 of your issue for 2nd March, of the communication made by Prof. Perry and myself, "On the Efficiency of Incandescent Lamps with Direct and Alternating Currents," to the Physical Society, on the 25th February, there is a misconception which, as it involves a question of principle, and not a mere matter of detail, I should like to correct. The expression for the true watts given to the circuit is correctly stated in your report as

$$\frac{r\tau\sqrt{V^2 . A^2}}{\sqrt{L^2\pi^2 + r^2\tau^2}}$$

but A and V are not "the mean value of the potential in volts, A that of the current in amperes," but the square roots of the mean squares, which differ by 10 per cent. from the mean values when the P.D. and the current are sine functions of the time. The figure correctly represents the apparatus employed in the investigation, but it is inconsistent with the statement in the report that "r is the resistance of the dynamometer, and L its coefficient of self-induction." r and L refer to the lamp only, and therefore L was practically negligible, so that the product of the square root of the mean square of the volts into the square root of the mean square of the amperes correctly measured the power given to the lamp.

The numbers 3·3989 for direct currents and 3·3955 for alternate currents are the watts per candle, and not, as stated, "the light obtained from the lamp in terms of the standard candle for the power of one watt."

I should like to take this opportunity of thanking Messrs. Shepherd and Wheatley, two of the students at the Central Institution, for their assistance in conducting the investigation.

While writing this my eye has caught Mr. Pollak's question in his letter, in the same issue of your journal, on a totally different subject—viz., "Electric Traction." I may therefore mention that the magnetic device of ours for use in working long electric railways with little leakage, to which Mr. Geipel was, I presume, alluding, is referred to on page 15 of our patent, No. 783, dated 1881, for "Electrical Conductors," and which therefore antedates that of Messrs. Pollak and Binswanger by *five* years. Regarding Mr. Pollak's statement, "As I know Profs. Ayrton and Perry before this date (1886) had not proposed tramways on the parallel system, &c.," I must ask him to kindly refer to my lectures delivered some years before that date on electric railways worked on the *parallel* system at the Royal Institution, London ; the Royal Society, Dublin ; the Birmingham and Midland Institute, &c., which were not only reported and illustrated at the time in your own and other scientific periodicals, but also in the *Graphic* and other newspapers of general interest.—Yours, &c.,

W. E. AYRTON.

ELECTRIC TRACTION.—CLOSED CONDUIT SYSTEMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Charles Pollak asks me to point out dates and papers in connection with *the system of making contact by magnetic attraction* invented by Profs. Ayrton and Perry.

I find the patent specification which contains the improvement to which I refer is dated 24th February, 1881, No. 783—that is, two years prior to the specification alluded to by Mr. Pollak; although in writing my paper I did not look up any such matter, but merely wrote the impressions I had formed on the subject from various sources.

I have read over, however, Ayrton and Perry's patent No. 783, 1881, from which I extract the two following paragraphs:—

"Our improved apparatus consists of an insulated wire cable, or other conductor or conductors, placed either alongside, above, or underneath the railway, or in any other suitable position, and the insulation of which is maintained by gutta percha, india rubber, &c., or by paraffin or other oils, or by its being supported on insulators. This conductor, or conductors, is automatically, or at will by a signalman or other person, electrically connected successively to one or more sections of a rail in the neighbourhood of the moving train. This rail, which may or may not be that on which the train runs, and which may be rigid or somewhat elastic, is divided into sections fairly well insulated from one another and from the earth by the methods described further on. Since then leakage to the earth of the current which propels the train can only take place from that section or sections of the rail which are at any moment electrically connected with the continuous insulated conductor; the loss of power by leakage of electricity to the ground will be very much less than in the case of a single imperfectly insulated rail, such as has been hitherto employed for electric railways, and which if of considerable length, with its corresponding large number of points of support, would possess a very large number of points at which leakage of the motive electric current would continually take place."

"Instead of mechanical plungers, shown on sheet 2, for automatically connecting the main cable with the section just entered by the train, and for automatically disconnecting the main cable from the section the train is leaving, we may use electric means for this purpose, ... or we may employ a magnetic arrangement, depending for its action not on the weight of the train but on its magnetic mass."

In conclusion, I must say that I fail to see how any distinction can be made in the application of this system, viz., the making contact by magnetic attraction on the *series* or *parallel* system; the object of the improvement is evidently to overcome the difficulty of leakage in long lines.

As to the validity of the several patents, it is for others than myself to pronounce.—Yours, &c., W. GEIPEL.

Edinburgh, March 5, 1888.

ON THE MEASUREMENT OF MAGNETIC LAG.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following is the method of procedure to find the lag of magnetisation behind the field produced by the currents, in the case of secondary generators, to which I alluded the other evening at the meeting of the Society of Telegraph-Engineers and Electricians in the discussion following the paper by Mr. Kapp upon secondary generators.

To keep the formula quite general I will suppose that three dynamometers of different constants, A, B, C, are used, and I shall refer to each dynamometer by these letters, as 'the dynamometer A,' it being understood that if the current through the dynamometer A is I, while the reading is a_1, then $\frac{I^2}{2} = A a^1$.

Dynamometer A is placed in the primary circuit, and its reading is a_1.

Dynamometer B is placed in the secondary circuit, and its reading is a_2.

Dynamometer C has one coil in the primary circuit and the other coil in the secondary. Its reading is a_3.

The three observations are made simultaneously.

m and n are the number of turns in the primary and secondary coils respectively.

Then the angle of magnetic lag θ is given by the equation,

$$\tan\theta = \frac{C a_3 - \frac{n}{m} B a_2}{\sqrt{A B a_1 a_2 - C^2 a_3^2}}.$$

If the dynamometers are all similar $A = B = C$, and if the number of turns in the primary coil is equal to the number of turns in the secondary coil $m = n$

In this case

$$\tan\theta = \frac{a_3 - a_2}{\sqrt{a_1 a_2 - a_3^2}}.$$

It will be observed that the numerators only involve the observations on two of the instruments; thus, only these two dynamometers are necessary to determine whether or not the lag exists; for if it does not exist, these numerators vanish.

The tangent of the angle of lag is proportional to double the hysteresis coefficient, or to the coefficient of magnetic self-induction, the induced field being proportional to the rate at which the magnetisation is changing, and therefore having its phases in quadrature with the magnetisation itself.—Yours, &c., THOMAS H. BLAKESLEY.

Royal Naval College, Greenwich, March 6, 1888.

INDUCTANCE AND RESISTANCE IN TELEPHONE CIRCUITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In answer to your correspondent F. B. Hawes, who writes under the above title in the March 2nd number of your journal, p. 452, I am sorry to be unable to do more at present than to refer him to the note at the end of Section XLVII. of "Electromagnetic Induction and its Propagation," in *The Electrician* for December 30, 1887.—Yours, &c.,

March 3, 1888. OLIVER HEAVISIDE.

[We may also refer our correspondent to an important paper on the same subject by M. Vaschy, an abstract of which will be found in our present issue.—ED. *E.*]

THE STABILITY OF TELEGRAPH WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With respect to the correspondence on the subject of springs for telegraph wires, the principal failures in the case of the wires of this company in the last snowstorm (January, 1887) arose not from the breakage of the wires, but from the collapse of the supports under the superincumbent weight of snow.

I fail to see in what way springs would relieve the supports of this extra burthen.

An increase of the dip would somewhat increase the length of the span and the snow-carrying length of the wire; the strains on a straight line are, of course, balanced at the insulators, and if the wires are strong enough, as in many cases they are, to carry away the supports when steadily loaded up to their utmost capacity, nothing short of removal of the load of snow will reduce the weight to be carried.

The real difficulty is not to prevent the wire breaking but the supports from giving way, and it should not be forgotten that, except in the case of terminal insulators, there is no strain whatever on the poles on a straight line, but only the weight of the wire and its burthen to support.

Even in the case of a lateral strain being added, as in the case of wind, the strains are still balanced at the insulator, and the stress on the support is only that due to the surface pressure of the wind acting on the wire as a sail.—Yours, &c.,

F. HIGGINS.

17 and 18, Cornhill, London, E.C., March 5, 1888.

THE STABILITY OF TELEGRAPH WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Preece compliments the advance of my education on the above subject, but I think your readers will see that I have not changed the ground I occupied when I first wrote you (see *The Electrician*, 21st October, 1887). Meanwhile Mr. Preece has been making giant strides himself. He recognises

Digitized by Google

at last that the elasticity of the wire must be allowed for: and he does not offer one word in corroboration of the table of dips and stresses which he upheld at the British Association only seven months ago.

But Mr. Preece is really too flattering when he calmly assures your readers that I have "calculated a certain curve, and *caused my apparatus to reproduce it!*" Your readers know quite well, without his telling, that I calculated the curve, and that my calculation, unlike his own, proved substantially correct. But that I worked the miracle of making the curve suit my calculation would make a wizard of me, when, as Mr. Preece (apparently at a loss for better argument) very properly shows, I am not entitled even to rank as a telegraph engineer!

Then Mr Preece adds, "his data are wrong, his curves are wrong, and he is working in the dark." It is a pity to spoil this rhetoric, but if Mr. Preece will come to Sunderland, I will repeat the experiments in his presence, and prove to him in broad daylight that the curves are right and the data right.

If he will not come, then let him issue figures of his own, and if they differ substantially from mine I will undertake that they shall share the fate of the Manchester table of dips and stresses. By the way, how came that table to be put forth, *if* (as Mr. Preece states) "responsible engineers had performed more than a quarter century ago similar experiments," which should have prevented Mr. Preece from neglecting to allow for the stretch of the wire?

Mr. Preece does not condescend to enlighten your readers as to the nature and extent of the "errors" which he alleges I have committed in my experiments; but he axiomatically says, "A telegraph wire is freely suspended between two rigidly fixed points;" as if anybody would dream of disputing what everyone knows. And he oracularly adds, "We have to regard what takes place in only one span;" which is precisely what we did regard in the Monkwearmouth experiments. Then he says, "Omitting external stresses, the changes of form in this span are changes due to variations of temperature. The changes of strain are changes due to its own elasticity," which not very original observation it is not for *me* to dispute. Although these axioms have no proper bearing on the experiments I have published, I may as well point out that change of form in a span of wire is *not* due alone to variations of temperature, but is due also to elasticity. Likewise, changes of stress are not due alone to elasticity, but also to expansion. Expansion and elasticity are the *component* contrary working forces whose *resultant* is the change, both in form and stress, of the wire. Thus Mr. Preece's *axioms* will not hold water any better than his *table*.

Mr. Preece suggests that I erect a span of wires and watch "their vagaries" for years. Happily I am spared this necessity, for a long span of many telephone wires passes within a stone's throw of my parlour window, and I have for more than four years had the opportunity of studying the same; even now, as I write, a strong gale is whistling through the wires. Mr. Preece also advises me to experiment on the breaking strength of wires. This I have done, and have come to understand, at least to some extent, the relations between the limit of tenacity and the limit of elasticity, and the important bearing of these relations on the life and duty of the wire.

If, by increasing the tensile strength of the wire and frequency of posts, the conductivity and *insulation* are improved without considerable increase of first cost and maintenance, then Mr. Preece may go on making erroneous tables and "smiling at springs" with impunity.

But if, on the other hand, by means of this officially approved innovation the cost be increased and the insulation lessened, the intelligent taxpayer will fail to see where the smile comes in.

Mr. Preece has sufficiently proved that he is not incapable of living and learning, and his last letter is so pregnant of "changes of strain due to elasticity" that I think, if he will only allow his mind free play, he will arrive at conclusions, regarding the saving power of springs against stresses from ice, snow, wind, falling trees, &c., which will enable him to agree with the truth I have from the outset endeavoured to demonstrate, and especially in my unanswered letter and diagram with tables (*The Electrician*, 9th Dec., 1887).

Then he will regard the springs with a "smile" of intelligent welcome rather than of prejudiced derision.

Mr. Bozon's new bull about my having, as he supposes, "forgotten to allow for the spring balance and vice," is not less amusing than his memorable buffers of imperishable rubber. His mistake is really too childish for me to occupy your space in explaining; but if he will send me his private address, I shall be pleased to do my best to put him right on the point.—Yours, &c., FRANK CAWS.

Sunderland.

THE TERM "MAGNETIC RESISTANCE."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: First, I did not mean to say that M. Hospitalier put μ in the numerator in his "magnetic resistance;" μ was a slip for $1/\mu$. I noticed the error when the letter was printed, but thought it too obvious to require correction. To make sure there is no misunderstanding, let me say definitely that by "magnetic resistance" I presume is meant the total "magnetomotive force" divided by the total induction. In a closed circuit transformer this would be $0{\cdot}4\pi$ times the magnetising ampere turns divided by the total induction.

Having shown, I hope, that I have not misunderstood M. Hospitalier, let me say I fear he has misunderstood me in some way. I said nothing about electrostatic resistance, and do not see that its being of the nature of a slowness is to the point.

A digression which has nothing to do with M. Hospitalier may be allowed. Some two years ago I pointed out that it is nonsense to speak of resistance in the electrostatic system as of the nature of a slowness. It has nothing to do with slowness. The idea arises from want of clearness as to the physical meaning of $\frac{[T]}{[L]}$. The symbol $\frac{[T]}{[L]}$ simply shows what number the number of units representing a slowness or a resistance in the electrostatic system must be multiplied by if the fundamental units are changed. It has nothing to do with the nature of resistance. For instance, resistance is of the same nature whether it is measured in electrostatic or electro-magnetic units; the only difference is in the units, one of which is v^2 times as large as the other. When I wrote on this subject before I found that many thought I was talking nonsense, because no one could suppose that resistance was velocity; others said that $\frac{[L]}{[T]}$ meant that resistance, in electro-magnetic measure, is measured by a velocity or by velocity. This also means nothing, as the slider arrangement always used as an illustration can be equally well used to show that the current or the electromotive force varies as the velocity.

That there is much mental confusion on these points is obvious from the unintelligent way the "dimensions" are copied into text-books. It is hardly likely that Maxwell, who wrote as a physicist more than as a mathematician, did not keep the physical interpretation before him; but the fact remains that he gives [0] as the change ratio of such quantities as specific electric, and magnetic inductive capacity, and this has been blindly copied, I think, by every English text-book.

Returning to M. Hospitalier's letter, I am afraid the *lettres de ronde* will be often confused with German capitals. For instance, in my letter I particularly desired the printer to use German capitals, and he used *lettres de ronde*. As to the vector question, it is, of course, of little importance; but it is worth while calling attention to it. These German capitals have the disadvantage that one cannot tell what letters they represent without frequent reference to a dictionary. A suggestion, due to Dr. Fleming, is to use thick or block letters for vectors. Why not use these instead of Maxwell's when they are to represent quantities not considered as vectors? Of course, *lettres de ronde* will do as well if they are a fount in universal use.

I have written at some length, not with the wish to be too critical, but because M. Hospitalier is likely to do more for a universal notation than all the rest of us together, and so it is of the highest importance that he should start fair, and I feel sure he will himself invite criticisms and opinions. In England,

Digitized by Google

Maxwell is looked upon as the chief text-book, and it is to be feared that if M. Hospitalier departs from Maxwell's ideas and notation it will prejudice the introduction of his own.—Yours, &c., JAS. SWINBURNE.

BATTERY *VERSUS* ALTERNATE-CURRENT TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I for one shared the disappointment of which you speak in your last week's leader at not hearing from Mr. Crompton something more definite as to the cost of lighting on the battery system. At the previous meeting Mr. Crompton challenged the other side to produce actual figures showing the cost of distribution by transformers, and he said he was prepared to go into the fullest details upon the basis of his own experience with batteries. It is to be hoped that Mr. Crompton will still take an early opportunity of giving us the facts as to first and prime cost (including renewal of batteries) in some well-known installation, say, for instance, the Vienna Opera House, which he referred to at the meeting. Meanwhile, in common with most other electricians of my acquaintance, I find it very hard to believe that the system of low-tension distribution, plus batteries, whose depreciation rate is still an unknown quantity, while their first cost is enormous, can possibly compete in point of economy with a system in which the life of the transformer may easily be twenty times as prolonged as that of any known battery, and in which the cost of distributing mains and transformers together is but a fraction in comparison with that of a battery system. It is for Mr. Crompton to prove the contrary—if he can.—Yours, &c., C. W. S. CRAWLEY.

Castletown-road, West Kensington, March 8, 1888.

TELEPHONIC COMMUNICATION WITH SHIPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to your remarks about telephonic communication with ships at anchor in your issue of Dec. 23, 1887, it might possibly interest you to learn that we established such communication with the ships of the Orient and Messageries lines, now nearly two years ago, and that it has been working well ever since with rare exceptions.

I enclose an extract from the *South Australian Advertiser* of March 30, 1886, and shall be glad to furnish you with description and sketches of arrangements if you deem it desirable.—Yours, &c., C. UNBEHAUN, Telegraph Department,

Adelaide, Feb. 6, 1888. Adelaide, S.A.

[We should be glad to receive the description and sketches from our correspondent. The extract referred to will be found amongst our "Notes."—ED. *E.*]

THE INDUCTOR DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I see in your last issue in the report of the discussion of Mr. Mackenzie's paper at the Society of Telegraph-Engineers that Mr. Esson prophesies that the magnets of my dynamo will get hot. Will you allow me to allay his anxiety on this point? In the machine partly constructed and now under trial, both the inductors and the magnet cores, being thoroughly laminated, remain quite cool.

The field, or primary magnetism, is slightly unsteady, but no bad effects are perceptible from this cause. It is, of course, easy to make the magnetism quite steady by properly proportioning the inductors.—Yours, &c., J. A. KINGDON.

Kidsgrove, March 6th, 1888.

REINBOLD'S ALUMINIUM PROCESS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to your correspondent, who asks for information in reference to Mr. Herman Reinbold's process for the electro-deposition of aluminium, a notice of which appeared in your paper of the 3rd ult., I may say that it strikes me that the formula given is a somewhat remarkable one, and in the hands of inexperienced persons might involve very serious consequences.

According to the recipe 50 parts of alum are dissolved in 300 parts of water and 10 parts of chloride of aluminium added, the whole being heated to 200 degrees and allowed to cool, whereupon 39 parts of cyanide of potassium are to be added. Now, if it be the anhydrous chloride of aluminium that is to be employed, this would at once be decomposed by the water, with formation of alumina and liberation of hydrochloric acid; or if the hydrated chloride were used, this would be in a highly acid condition. To this acid mixture we are to add 39 parts of cyanide of potassium, which it is evident would be immediately decomposed by the hydrochloric acid and the alum, hydrate of alumina being precipitated and hydrocyanic acid set free in abundance. How such a process is to act I am at a loss to conceive. Cyanide of potassium in the presence of an acid solution like that of alum, would be risky enough if the operations were conducted under the nose of the operator, but with free hydrochloric acid also in the liquid even a very small experiment would be dangerous in the hands of persons unacquainted with the deadly nature of cyanogen vapours. Since the combination given in the formula would undoubtedly result in the precipitation of the whole of the alumin, the deposition of metallic aluminium from such a mixture would, I should say, be an impossibility.—Yours, &c, ALEXANDER WATT.

THE ELECTRIC LIGHTING ACT (1882) AMENDMENT BILL.

In the House of Lords on Monday, March 5, LORD THURLOW, in moving the second reading of this Bill, said that if he could have had an assurance from the Government that they would be willing to take this matter in hand, he would not have troubled their lordships on the present occasion. He desired their lordships to regard this question from the point of view of health, of science, of more light, of safety, and of the preservation of property. The object of the Bill was to remove what had proved to be prohibitive restrictions upon an industry which was deserving of every support. The restrictions imposed by the Act of 1882 had acted very harshly. The President of the Board of Trade, replying last week to a question in the House of Commons, said that since the passing of the Electric Lighting Act of 1882, fifty-nine provisional orders and five licenses had been granted to companies, and fifteen provisional orders and two licenses to local authorities. The President of the Board of Trade was not aware that in any single case where these powers had been obtained they had been exercised. Such was the crushing effect of the Electric Lighting Act of 1882. Still he wished to say a few words in praise of that measure, which it was the object of this Bill to amend in only one or two small but important particulars. The Act of 1882 was a most elaborate measure for dealing with a then almost unknown science. It successfully prescribed safeguards against dangers which had only since become manifest, and its object was to impose checks on rash and ill-considered schemes. It now only required trifling amendment to allow the industry to proceed, and he claimed that the time had arrived for action in that direction. In the United States there were over 120 electric light companies paying dividends from 6 to 14 per cent., in Germany there were 604 companies, and in almost every large town in Italy electric lighting was making progress. It was only in England that the science was comparatively at a standstill, and he hoped that state of things would not be allowed to last much longer. The present time was propitious for several reasons. There never was a time when a larger amount of capital was lying idle or when there was a larger number of unemployed seeking work and finding none. Many of their lordships had no doubt visited factories lighted by gas full of toiling men, women, and children from 6:30 a.m. to 6:30 p.m., and had noticed the vitiated state of the atmosphere. The difference between that and a factory lighted by electricity was manifest in a moment. It was like being transported suddenly to another planet. Workmen who had been employed in factories lighted with electricity had told him that nothing short of starvation would induce them to work again in factories lighted by gas. It was the same in the case of mines. Electric lighting would minimise the dangers which now occurred through naked lights or faulty lamps. Then as to fires in the metropolis, Captain Shaw's report showed that the total number of fires in 1887 was 2,363, and no less than 671, or 30 per cent., were directly attributable to causes connected with existing systems of lighting. These figures did not include 691 fires the origin of which was uncertain, and of these at least 30 per cent. might fairly be said to be due to the same cause. Then as to the destruction and damage to property. Some of the first tradesmen in London had told him that they had effected great saving since they had substituted the electric light

Digitized by Google

for gas in their show rooms and shops. It was also well known that the use of gas was very prejudicial to books, and the employment of electric light in libraries would be a great advantage. The Bill was precisely similar to the Bill which was passed by this House last Session, and it proposed to extend the license granted by provisional order to any company from 21 years to 42 years. The period of 21 years fixed by the present Act was found to be too short and to be insufficient to allow electric lighting companies to recoup themselves. The Board of Trade acceded to this view, and this extension of the life of the provisional order would render the clauses with regard to the terms of purchase of less importance. He would therefore be willing to strike out of the Bill all reference to the purchase of "the goodwill," which he understood had hitherto been a stumbling block and a cause of opposition to the Bill. In bringing forward this measure he was solely actuated by a desire for the public interest. There existed at present a great want of employment, and yet, as was well known, there was a vast amount of capital waiting for investment. If the present Act was amended as this Bill proposed, he believed that £100,000,000 of capital would thereby find useful employment (hear, hear).

The DUKE OF MARLBOROUGH said the Bill did not appear to contain any regulations as to the laying down of the electric cables. At present these lines were growing in number and were being run over everybody's houses without the assent or consent of householders, and he thought that it should be defined in any Bill dealing with this subject what the rights of electric companies exactly were. There had, so far as he knew, been no decision in the law courts upon the point. At present a quantity of telephone wires were to be seen running in every direction in the metropolis. The cables for electric lighting would be still more dangerous. They would in time become a great nuisance, and if the Acts dealing with electric lighting were silent on the point it would hereafter be said that Parliament had unreservedly conferred on these companies the right of running these cables over houses as at present.

The EARL OF CRAWFORD and BALCARRES agreed that the Electric Lighting Act required amendment, but he thought they should deal in a thorough manner with this subject and not merely with a single clause. In 1882, when the first Act was passed, a determination was formed that the promoters of electric lighting schemes should not enjoy a monopoly, and it was accordingly resolved that when cables were laid in the streets of any town by an electric company its work should be purchaseable by the local authority. Another provision of the Act laid down that no work should be undertaken by a company without a license from the Board of Trade, or a special Act, or a provisional order. These two provisions had been fatal to the measure, Licenses and provisional orders had been applied for, but no work had been done. He suggested that the promoters of a scheme ought to be allowed to make their own arrangements with the local authority. Let the company pay rent for the use of the mains which they placed under the streets, and let them be absolved from the obligation of supplying light to every corner of a given district when there might be no chance of a reasonable return for their outlay. He looked forward to the day when companies would be able to lay their cables underground with a good prospect of success; but he asserted that the risks attending exposed electric mains were fewer than the risks which attended either telephone or telegraph wires. When snow fell upon an electric light main it inevitably melted, but it accumulated on other wires with the result that serious accidents were not uncommon. He hoped that the Bill before their lordships would be read a second time. Hereafter he intended to place before them a Bill of his own.

The EARL OF ONSLOW said that the Bill as explained by the noble lord opposite was much less important than it was as printed. There was a clause in the Bill which covered a great deal of ground and repealed a provision of the existing Act; but he understood that when the Bill was considered in committee the whole of that clause would be withdrawn in order that to the term of twenty-one years during which provisional orders must now run a further term of twenty-one years might be added. The Bill, as it was amended, did not appear likely to be productive of great harm, and he was prepared to assent to the second reading on the conditions the noble lord had suggested.

LORD HERSCHELL was not quite sure he understood what it was the Government was prepared to assent to. As far as he could gather it was that the Act of 1882 was to be amended by substituting 42 years for 21 years. If no other alteration was to be made he much doubted whether the Bill would have the effect desired. In this country we had not made the advance in electric lighting which had been made in other parts of the world. He had long desired to avail himself of this important improvement, but he had found it to be utterly impossible for the reason that the Legislature had put impediments in the way of the spread of this invention which was not put in its way in any other country. He believed that in the South Sea Islands the electric light was more used than it was in London. (Laughter.)

The MARQUIS OF SALISBURY: I sympathise entirely with the remarks of the noble and learned lord, but I cannot help remembering that he was a member of the Government which passed the Act that he has denounced with so much vigour. (Laughter.) When I sat exactly where he is sitting now I pleaded in vain for a greater extension of the number of years, and I prophesied the results which have actually occurred. I rather think the noble and learned lord opposite is imitating those sectaries of the Middle Ages who went about laying stripes on their own shoulders for the sins they had committed. The noble and learned lord had held up to our admiration the example of the South Sea Islands in this matter; however, I am too delighted to see that the noble and learned lord recognises the difficulty in which we find ourselves to be critical as to the precise means by which his conversion was brought about. It is a matter of regret that we have not been able to make greater use of this invention, considering the vast amount of capital we have at our disposal and the great need in our smoky towns of diminishing the unconsumed carbon in our atmosphere. Although the Board of Trade has, acting under the guidance of the distinguished statesman who presided over it during the term of office of the noble and learned lord, to some extent, I am afraid, since that time, exaggerated the danger of liberty in this matter, it is fair we should remember that we have had very severe lessons in respect of leaving uncontrolled powers to municipalities and public authorities to make binding bargains with trading companies (hear, hear). On the subjects of water and gas we have had very severe lessons, and we are now struggling under the difficulties that have arisen. The noble viscount near me (Viscount Cross) was said some years ago to have wrecked the Government by the proposals he made for the purchase of the undertakings of the London water companies. We now only wish that the proposals which were then denounced could be revived with success and carried into effect. We have bound ourselves by promises to the water companies which give them a hold upon us that I do not know we shall ever shake off. Undoubtedly, the price at which this essential article may be furnished must have very considerably affected the progress of sanitary measures so much required in many parts of the metropolis. We have contrived to make some agreement with the gas companies. Twenty years ago we woke up to the fact that we had allowed most improvident agreements to be made with them, that we had allowed them, on the faith of competition which did not exist, to charge enormous prices. At the present moment, in regard to gas companies, we are under difficulties which could not have been foreseen by our forefathers when these terms were made, or I am convinced that the measures which they allowed to pass would have been seriously modified. The truth is that in both these cases we have made exceedingly bad bargains, and we are bound by them; and, therefore, it is not wholly unreasonable that in dealing with this new element we should approach it with some amount of caution. I quite believe we may have been too cautious, and may have run into an opposite extreme, and, by hindering the production of the electric light at the cheapest prices, may have prevented the development of this new industry. If the noble and learned lord can show us that the terms we ask can be reasonably modified no feeling of self love will prevent us from making any alteration which your lordships may think desirable. I feel that the whole question of the expediency of giving this power to the municipalities has of late years been too much assumed without sufficient proof, and we should be cautious about surrendering ourselves wholly to them and preventing that protective competition of private companies which is so desirable in the interests of the community at large (hear, hear).

After some remarks from the EARL OF KIMBERLEY, the Bill was read a second time.

GERMAN UNION TELEGRAPH AND TRUST COMPANY (LIMITED).

The report of the Directors of this Company for the twelve months ended December 31, 1887, states that the total receipts during the twelve months amount to £15,368, which, with a balance of £31 brought forward from last account, make a total of £15,399. The expenses for the same period amount to £892; of this sum £750 is provided by the German Union Company of Berlin. Out of the receipts an interim dividend of 5s. 9d. per share was distributed on January 17 last, and the Directors recommend the payment of a further dividend of 8s. 3d. per share, making a total distribution for the year of 14s. per share, free of income-tax, or at the rate of £7 per cent. per annum (as against £6 paid last year), leaving a balance of £156. 3s. 5d. to be carried over to next account.

The proposal of the Imperial German Government for the acquisition of the cables and property of the Berlin Company has been accepted, and an agreement on the terms sanctioned by the extraordinary general meeting of this Company of November 23th, 1887, has been entered into, subject to the formal approval of the Reichstag, which is daily expected. The result of the agreement will be, so far as can at present be foreseen, that the Berlin Company will begin to go into liquidation in April next, and that the shareholders of this Company will receive a return in respect of their capital early in 1889, when the Government will pay the purchase money.

The exact sum to be paid to the shareholders of this Company cannot be determined at present, but it will probably be about par—that is, £10 per share, less expenses of liquidation, which will make a fractional reduction.

NEW COMPANY REGISTERED.

THE ELECTRICAL WORKS CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—Registered by George Annesley Grindle, 19, Great Winchester street, E.C., with a capital of £2,000 in £1 shares. Object, to carry on the business of electricians and electrical engineers.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts for the week ended 2nd March amounted to the sum of £4,435.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of February amounted to £51,261, and to £46,900 in the corresponding period of 1887.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of February, amounted to £38,795, and to £35,553 in the corresponding period of 1887, showing an increase of £3,242.

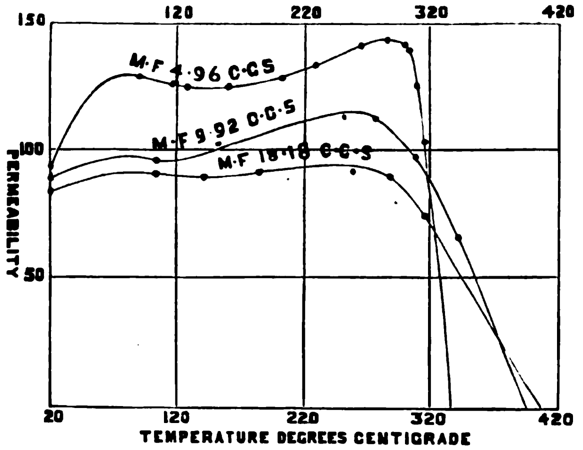
PHYSICAL SOCIETY.

At the meeting on Saturday, February 25, two other papers of electrical interest, in addition to the one reported last week, were communicated to the society. The first of these was by Mr. Herbert Tomlinson, B.A.,

"ON THE TEMPERATURE AT WHICH NICKEL BEGINS SUDDENLY TO LOSE ITS MAGNETIC PROPERTIES."

The critical temperature for nickel is well known to be higher than that of iron, and from 300° to 400° C. is generally given as the limits of temperature within which the former metal loses its magnetic susceptibility. In the present communication the author describes the results of a series of experiments on the permeability of nickel at different temperatures, and for various magnetising forces.

These results are shown for three values of the magnetising force by the curves in the diagram below, in which the temperatures in degrees centigrade are taken as abscissæ, and the corresponding values of the magnetic permeability as ordinates.



It will be seen from the diagram that the greater the magnetising force, the higher is the temperature at which magnetic susceptibility ceases, and that this loss of susceptibility is much more sudden for low than for high values of the magnetising force. The suddenness is also considerably diminished by the presence of any impurity.

In order to see how sudden the loss would be in the case of a very thin metal of the greatest attainable purity a piece of thin brass wire was coated with electrolytically deposited nickel, and was suspended by a platinum wire between the poles of an electro-magnet, and when unmagnetised was kept by the torsion of the suspended wire in a position at right angles to the lines of force.

The wire was then heated up to about 500° C. by means of a Bunsen flame, the circuit of the electro-magnet was closed, and no effect was observed. The circuit was then broken, so that only the residual magnetism could affect the nickel-coated wire, and the latter was allowed to cool. This experiment was exhibited to the society, and a few seconds after the flame had been withdrawn the wire was seen to turn through a right angle with startling suddenness, and was then attracted and remained adhering to one of the poles of the electro-magnet.

Mr. SHELFORD BIDWELL asked whether the first maximum shown in the curve for magnetising force 4·96 was always found, or whether it was an accident of the particular experiment. He would like to know whether a small difference of, say, 5 degrees at the ordinary temperature of the air would have any sensible influence on the permeability, as some experiments which he has not yet published suggest that this may be the case.

Mr. MORDEY observed that after the withdrawal of the flame, of which some experimental forms had been tried, a perceptible time appears to elapse before the nickel becomes magnetic. This was a point of practical importance in relation to thermo-magnetic generators, a great defect in which was that, making some 200 or 300 revolutions a minute, and having imperfect provision for cooling on emerging from the flame, there could only be a small fall of temperature. He would like to know if Mr. Tomlinson had made any experiments on the practical limit to the rapidity.

Mr. TOMLINSON, in reply, stated that the maximum referred to by Mr. Bidwell was found to occur regularly, and he thought that there was much too great a tendency to smooth down the observed irregularities in drawing magnetic curves. He pointed out that the diagram clearly showed that the rapidity of increase as well as of decrease in the permeability depends on the amount of the magnetising force.

In the absence of Mr. W. W. Haldane Gee, the SECRETARY then read his paper on

"EXPERIMENTS ON ELECTROLYSIS."

The author finds that when a dilute solution of sulphuric acid is electrolysed with palladium electrodes, if the current is reversed, streaks such as would be produced by a dense liquid streaming downwards are at first seen proceeding from the pole which is now the anode, and as long as the streaks continue no gas is evolved from the anode. The streaks disappear, and the evolution of gas begins after a time, depending on the duration of the current before reversal, on the strength of the current, and on the size of the electrode forming the anode. Removing the electrode and cleaning it by rubbing prior to reversal does not have any influence on the result; but if the electrode is heated to redness before being replaced the streaks are no longer formed. The author therefore concludes that they are due to hydrogen occluded in the electrode forming compounds with SO_4. Similar results are obtained by the electrolysis of pure phosphoric acid and of solutions of the caustic alkalies. The author states that the presence of these streaks exercises an effect on the resistance, which will be made the subject of a further communication.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

STUDENTS' MEETING.

A meeting of the students took place on Thursday last, the 1st inst., Mr. W. M. Mordey being in the chair.

Mr. W. E. Hayne opened a discussion upon Mr. Cockburn's paper on "Safety Fuses, &c.," describing several improvements, one of which is to replace the leaden pellet, an essential part of Mr. Cockburn's fuse, by a small spring; a duplex cut-out was also mentioned (devised by himself and his brother), in which a second fuse is thrown into circuit after some definite time, useful in cases of accidental or designed short circuits, lasting only for a short time.

Messrs. Lamb, Hume, Rance and Mordey continued the discussion. A vote of thanks to the chairman terminated the proceedings.

ALTERNATE CURRENT TRANSFORMERS.

DISCUSSION.—(*Concluded from page 445.*)

Mr. MORDEY said the position of opposition to transformer distribution taken up by Mr. Crompton and Mr. Gordon rather reminded him of a certain historical person, who told the tide to advance no further; but with the difference, that whereas King Canute knew the sea would not obey him, the gentlemen who had spoken did not. He thought there was no doubt whatever, from what had been seen, on the other side of the Atlantic at any rate, that transformers had a very great future before them. Mr. Crompton said that the bottom would be knocked out of his argument if it could be shown that small alternating-current dynamos could be used and could be put in parallel. It was easy to knock the bottom out of the argument. In the United States machines were being run in parallel not only in one large station, but it had been done across rivers. A station on one side of a river is supplying mains connected with a network on the other side, as well as on its own side; and when it is necessary to put more power on the mains, the dynamos on the other side of the river are switched in. He did not think there was any serious difficulty. There was one objection he would like to make to the conclusion of Mr. Kapp's paper, and that was as to the use of low-tension networks with transformers. It seemed to him that the great advantage they had in transformers was that they got rid of the enormous cost of a low-tension network. Everybody had known that the cost of the copper in a low-tension distribution system had been a very serious item on the whole. It seemed to him that as transformers regulated so perfectly, and as they could be made to regulate even more perfectly than they did just in their simple state, and as they were undoubtedly very efficient indeed for small loads, and further, as loss in the main conductors could be at a practically small cost rendered of no practical effect whatever, it seemed to him that they got rid entirely of any necessity for the distribution network. They only wanted a distribution network that would help one part from another when the wires of any one part were not sufficient to carry a full current. He also disagreed with Mr. Kapp as to the danger of having separate transformers for every house. It might not be necessary to put them in every house, but he certainly thought that if some simple arrangement were made for cutting out a transformer when anything went wrong with it, it was the very best thing they could do. They might put a number of transformers right along the mains, and just one house would be cut out and no more when the transformer in that house went wrong. He even went so far as this, that in a big house like a hotel he would run the mains round outside the buildings; he would take the wires in at two or three places from the outside, and put transformers at those points. To that extent, perhaps, a network system might be used—that is, with the inexpensive primary rather than the expensive secondary conductors.

With regard to the employment of series or of parallel systems of connection he thought the advocates of the series connection of transformers forgot two difficulties. One was that the regulations of the constant-current system with an alternating-current dynamo was not at all easy. He did not know that that had been done yet. They could regulate and maintain a constant current with a direct current system, but for an alternating system this problem had not been solved in practice. The

regulation of the transformer alone only solved one part of the problem. They must have a constant current in the first place. When they had got a constant current it had been shown in two ways, by using lamps in series and by using Mr. Kent's very ingenious arrangement of the impedance coils, that it was possible to regulate the transformer. But they had got to start with the dynamo at the station, and they had not got over that preliminary difficulty yet. Then the second difficulty was that in a series or any other system what limited the engineer was the E.M.F. They could only work up to 2,000 or 3,000 volts. When they had got there they must stop and begin to increase their leads. He thought it was just as well to start with the parallel system, in which there was no problem that would have to be solved as they went on. But even if the constant alternate-current dynamo were forthcoming—and he felt that if such a machine were necessary to progress it would be produced—the self-regulating powers of the series system would be seriously hampered by the want of pliability found in the arrangement and connection of the lamp leads. If the simple series of lamps of large current and low potential were used the conductors would be large and troublesome; if groups of ordinary lamps in multiple series were employed, there were all the old complications of multiple series working; but single lamps of a group could be switched off by using impedance coils, though only with further complication and expense. Besides all these connections the series system would sometimes land us in the ludicrous position of having introduced a higher difference of potential in a house than we had outside of it. We should actually have to transform up instead of down from our high-tension mains. This would be particularly the case with a primary current of any considerable amount.

Mr. Bernstein had said that it was necessary to run the two mains for parallel work close together, but that this necessity did not exist with series mains. This was, he thought, a mistake, the necessity being equal in the two cases. It was thus probably not advisable to have a large open loop of a single main out and home, as was often done in continuous current work. This whole question of series or parallel connections demanded more than a passing notice, and the present was the time when the advocates of either system should justify their position. While admitting that for very small work (in which, however, it would be better to employ continuous currents) transformers in series might be used with advantage over transformers in parallel, he thought that for general distribution parallel connections would become almost universal.

He was very glad to see Prof. Ayrton making use of the calorimeter method of testing the transformer. He believed that method, even roughly carried out, could be made very accurate. About a couple of years ago he tried an experiment of this sort in the works of the Brush Corporation. He took a box—an ordinary packing case—and made it watertight, put a resistance coil in it, sent water through it, and sent a current through that resistance coil. He wished to measure the energy, the current and the difference of potential, which he did not know, being taken by independent observers. Using a bucket to measure the amount of water passing through this rough calorimeter, a couple of thermometers to take the temperature of the incoming and outgoing water, a result was obtained which worked out to within 4 per cent. of the actual energy as shown by the independent volt and ampere readings. That method could be easily applied as an absorption method of testing alternating currents. Unfortunately, it could not be used as a transmission method. It would thus be quite possible to carry out an electrical test without any other instrument than a thermometer.

It had been remarked by a previous speaker that it was not possible to decrease the speed of alternating-current dynamos for small loads because the alternations must be kept the same. Might he be allowed to mention a method by which it was possible to decrease the speed and to keep the alternations the same? He did not know that it was a very practical method, but at any rate it would work on paper. If they took an ordinary Gramme armature, and put a laminated field to it, and sent an alternating current at a given rate of alternation around the field, they would get from the ordinary continuous-current machine an alternating current with the same rate of alternations. If they kept a constant field they would get an electromotive force which would be directly proportional to the speed. Thus, it would be possible to vary the speed, without changing the rate of alternation, and to vary the current or E.M.F by a combination of speed and field regulation. The only thing that would be necessary would be to have a small machine which could be separately driven to excite the fields at a given rate of alternation.

He might, perhaps, mention another experiment that he had made. Mr. Kapp with his diagrams could at once see what was going to take place in a transformer, but some of them could not, and they liked to be able to see it if they could in a practical way. He wanted to be able to get something that he could look at that showed the lag in a transformer, and he should like to submit his method for criticism. Perhaps Mr. Kapp would tell him if it was a wrong method. If they were to take two transformers and join, say, the high-tension coils in series and send an alternating current through the low-tension circuit of the first transformer from a dynamo, as in Fig. 5, then, of course, they would get a current in the low-tension circuit of the second transformer, which might be used, say, for running glow lamps, and the momentary currents in the two coils would at the same time be (roughly) in the same direction, as shown in the figure. Suppose, then, that a certain difference of potential is maintained at the terminals 1 and 2 of the first transformer, as shown by a Cardew voltmeter, then there would be practically the same potential difference between terminals 3 and 4 of the second transformer, as would be shown by the voltmeter. The readings would not be quite alike, on account of the small loss due to the double transformation up and down. Now if terminals 2 and 3 were connected as in Fig. 5, and the voltmeter were placed across the terminals 1 and 4 it would, if the waves absolutely coincided, indicate the sum of the two previous readings; but if the waves did not coincide in phase the reading would be less than the sum of the two first readings, and the amount of this reduction might be made a measure of the difference of phase. Instead of connecting the two coils, as in Fig. 5, they may be joined together and to the voltmeter, as in Fig. 6, when it will be seen that the indication will be zero if there is no difference of phase, any indication on the voltmeter showing that the waves were not coincident. He had tried the experiment not only with two but with six transformers, connected in the same manner, in a series, and using the first and the last coils of the series connected, as shown, and in neither case had he been able to find any indication of lag, not even when there were many steps in the transformation processes.

Owing to the news (which he was sure they all very much regretted) of Mr. Gaulard's mental illness, he was a little reluctant to say anything about the theories put forward in Mr. Mackenzie's paper, many of which were open to question. He thought, however, one could not pass over the statement that it was not till the views of Faraday had been proved to be erroneous that it was found possible to make any advance in transformer work.

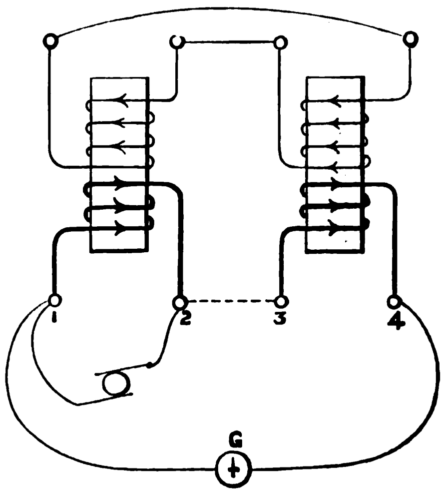


Fig. 5.—Connections of two transformers to give *sum* of E.M.F.'s on voltmeter G. Terminals 1 and 2 to dynamo, 3 and 4 open, or to lamps. Terminals 2 and 3 connected, 1 and 4 to voltmeter.

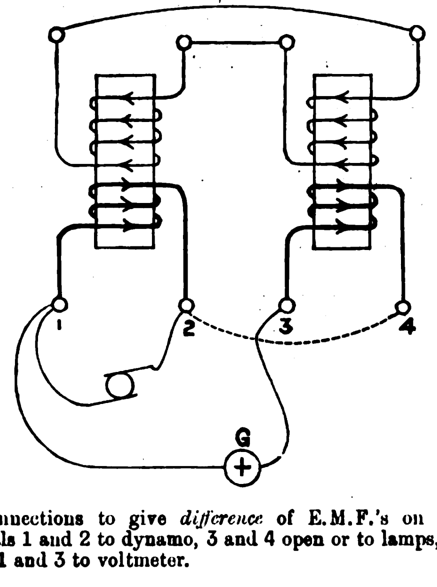

Fig. 6.—Connections to give *difference* of E.M.F.'s on voltmeter G. Terminals 1 and 2 to dynamo, 3 and 4 open or to lamps, 2 and 4 connected, 1 and 3 to voltmeter.

Mr. Willans, on being invited by the President to take part in the discussion, said that he could fully corroborate what Mr. Crompton had said about large engines working at very low power, although it would not be quite the same with condensing engines as with non-condensing engines.

Mr. T. Blakesley said he would touch upon some points that had been raised in the discussion, though not, perhaps, in chronological order. First with reference to the method which had just been pointed out of measuring the current phase. Some years ago he found a method of measuring precisely the phase between two alternating currents, and that method had met with such approbation from Signor Ferraris that that gentleman had done him the honour to adopt it as his own. It was this:—An ordinary two-coil dynamometer was employed. If they used these two coils in series they could measure the currents. They could apply this method first to one of the coils and then to the other, and then if they pleased they could send one of the currents through one of the coils, and the other through the other. This reading gave them without the smallest difficulty the cosine of the angle

Digitized by Google

between the two phases. Nothing was simpler, and nothing was easier to prove than that. If Mr. Kapp would try this method with his primary current and secondary current in his transformers he thought that that gentleman's mind would be enlightened as to some facts which he had put forward in connection with this subject Mr. Kapp had drawn a line representing the phase of magnetisation in his core, and he had made that correspond with the resultant field of the current in the secondary coil and the current in the primary coil. That, he maintained, was altogether at fault if hysteresis was a fact. If hysteresis was no fact, he had nothing to say on the matter, but Mr. Kapp himself agreed that there was a considerable quantity of hysteresis in the reversal of the polarity in the mass of iron. He would point out what he meant. O I_1 (Fig. 4, *The Electrician*, Feb. 10, page 340) and I_1 P together made up something which was the same phase as O P, the magnetic field due to the currents, but he denied that the magnetisation phase corresponded with that, and he denied it on this ground. If the magnetisation phase coincided with O P, the phase of the increase of magnetisation was at right angles to O P, and therefore its projection upon O P equalled nothing at all; and as the product of those two things was, in proportion to the hysteresis, the magnetic field and the increase of magnetism in the magnetic field—since that would be nothing—hysteresis could be nothing, and the magnetisation must, in fact, follow the field of magnetisation produced by currents. In fact, Mr. Kapp had left out a certain line which was an induced magnetic field due to the increase of magnetism itself. That was a fact he thought not very often recognised. If Mr. Kapp proceeded in a way that perhaps was rather too complicated to go into now, without much difficulty Mr. Kapp would work out his complete figure, only without the knowledge of one thing—viz., the coefficient of this hysteresis, which, of course, was a thing he was seeking; but if he applied this dynamometer method to find the phases between the two currents, the result would be that his figure would be completely determined and the hysteresis come out as a function of these dynamometer observations. He thought it was very right of Mr. Kapp to indulge in these geometrical figures, for he had done so very largely himself. He thought, however, that Mr. Kapp was wrong in placing in the same diagram things of an apparently different sort. Mr. Kapp had not kept all his lines of the same sort in the same diagram. If Mr. Kapp had been successful in his representation, perhaps he (the speaker) would have had to quarrel with him on another account, because he thought he himself had started this subject of representing phase geometrically before Mr. Kapp did, but he must entirely disclaim that figure representing the phases of the two magnetic forces by the resultant magnetisation.

Mr. ARTHUR WRIGHT, referring to Mr. Kapp's statement as to the superiority of the core transformer over the shell transformer, thought that Mr. Kapp had lost sight of the fact that nearly all the heat of the transformers was produced in the iron. The iron being outside, the shell transformer was better able to lose its heat than in the core transformer. If Mr. Kapp took that into consideration he would find that the shell transformer was very much better than the core transformer, as in this latter form the heat had first to warm the copper and so increase the loss in volts before it could escape.

In central station work it was very important to have a very small current indeed passing through the primary when the secondary was open, because in the case of a day and night supply, this current would mount up to a considerable value when there were many houses connected on the system. He thought it was most important to fully investigate each form of transformer on the basis of comparing the through current; by the through current he meant that passing through the primary with the secondary circuit open. With regard to safety, perhaps the simplest plan would be to connect the secondary circuit to its circuit earth through a very high-resistance inductionless coil, and to have a magnetic tumbler in which, when the tension of the secondary circuit was sufficiently high, would short-circuit the secondary terminals, and so fuse the primary fuses and cut out that transformer. That was simpler than any electrometer method, and he thought safer than the proposal of putting the secondary to earth. The question of getting over the difficulty of putting converters outside houses was most important, and he thought it might be overcome by putting the converter into cast-iron boxes with water-tight joints and placing a very small vessel of sulphuric acid to condense any moisture that might arise. He thought the danger of having a high-tension converter inside a house ought to be considered. With regard to Mr. Crompton's challenge about the cost of the unit, if Mr. Mackenzie was not going to give the figures asked for, he himself would be very happy to supply those that they had worked out at Brighton of the cost per unit throughout a whole year under all sorts of loads. Mr. Crompton in his figures must take into consideration the enormous cost per unit for depreciation of batteries and attendance, and he ought not to lose sight of the fact that management and superintendence mounted up to a very large figure. With regard to measuring the efficiency of a transformer by calorimeters, that seemed difficult in large transformers. It was very difficult, indeed, to put a 6 or 7-unit transformer in a vessel of water without losing a good deal of heat by radiation. With regard to Mr. Kapp's question as to the advisability of having one transformer to every house, or one to many houses, that he thought depended upon how the houses were situated in the system. Looking forward to the next two or three years, he thought it would be very difficult to get a number of consumers close together. However, when they did get two or three consumers close together, by all means let them put one converter for the group; for many years to come he did not think that would be the case, and for some time at least he thought they would be compelled to have separate converters for every house.

Mr. MADGEN referred to the statement in Mr. Mackenzie's paper that it was only when M. Gaulard came to the conclusion that induction apparatus constructed upon the theory founded by Faraday, and exemplified by Ruhmkorff, was unsuited for the purpose that success crowned their efforts. Perhaps Mr. Mackenzie would explain a little more fully what he meant by that. His reason for referring to this passage was that some time before Messrs. Gaulard and Gibbs commenced their experiments Jablochkoff had done a great deal of good work in this direction. Mr. Mackenzie went so far as to say that Jablochkoff and others had given a great deal of attention to this matter, but he thought Mr. Mackenzie had not done Jablochkoff sufficient justice. There was a drawing on the wall of Jablochkoff's transformer, which seemed to combine very important essentials, amongst others the closed magnetic circuit. That was considered by Jablochkoff to be the best form long before 1885. Of the modern types of transformers there seemed to be too much of a muchness; in fact, they were all very much alike. There was a strong resemblance between the Westinghouse transformer and the very excellent transformer designed by Kapp and Snell. Probably the most ingenious modern development in connection with transformers were the impedance coils of Messrs. Sharp and Kent.

Prof. SILVANUS THOMPSON said that he had read Mr. Kapp's paper with very much pleasure. He could not pretend to discuss it at that late hour. He appreciated very much the way in which Mr. Kapp had handled these geometrical diagrams. It seemed to him that Mr. Blakesley did not quite understand one point in those diagrams—as to what O P represented. It did not represent current, but the resultant magnetisation of the two currents. Although he appreciated much the good work Mr. Blakesley did three or four years ago, he thought they ought to acknowledge their indebtedness to an older source than even Mr. Blakesley for the use of geometrical diagrams for representing things of this kind. The thing was to be met with in the pages of Thomson and Tait, a treatise from which he supposed many of them imbibed many years ago. Coming to another point of Mr. Kapp's paper, he must confess that he could not agree with that gentleman in dividing transformers into core transformers and shell transformers. Where did the one begin and the other end? When did a core become a shell, and when did a shell become a core? All the same, he wished to express his indebtedness to Mr. Kapp for the excellent way in which he had put this subject before the society, and for the very impartial manner in which he had distributed his favours to rivals. He wished he could say the same of Mr. Mackenzie's paper. He was not present when the paper was read; but reading it over quietly at home he found much to seriously criticise. The statement that the theory founded by Faraday had to be abandoned was simply untrue.

Mr. MACKENZIE was understood to dissent.

Prof. S. THOMPSON: I mean this passage:—"It was only when M. Gaulard came to the conclusion that induction apparatus, constructed upon the theory founded by Faraday and exemplified by Ruhmkorff, was unsuited for the purpose, that a step was made in the right direction."

Mr. MACKENZIE was understood to say that there was some error there. He meant to say "as exemplified by Ruhmkorff." It did not interfere with Faraday's idea. It was an exemplification of the Ruhmkorff and Faraday idea.

Prof. S. THOMPSON said that the "Ruhmkorff and Faraday type" occurred two lines lower down. He thought that statement was rather extraordinary. Again, he did not understand what the result would be of dividing things into a class of Gaulard type and of non-Gaulard type. He saw here that in a transformer of the Gaulard type the secondary was "placed in an identical position with regard to the iron core as the primary." So far as those drawings show, the only way to do that was to have one wire of the secondary coil between one wire of the primary—that was to say that they must not have any coefficient of transformation at all. He admitted that it was a real novelty to use, as M. Gaulard had done, flat metal washers instead of wire coils; but the transformer so constructed was wholly unsuitable for distribution in parallel; it had a maximum risk of break down with a minimum performance. To put the secondary wire in "an identical position with regard to the core as the primary," as shown in Mr. Mackenzie's drawings, was to invite failure of insulation. If it did not mean that, he failed to see that it was very different from anybody else's transformer. He must refer to one other statement—a statement on page 3—that when Messrs. Gaulard and Gibbs first exhibited their system at the Westminster Aquarium, at the beginning of 1883, only one transformer was there shown in work, and this one was consequently "either in parallel or series" with the dynamo. That was rather a misleading statement. What was meant by two things being in parallel? It meant that the current flowed through both in parallel from the same point—from the same point on one side towards the same point on the other. But with one dynamo and one transformer, did they mean to say that those were in parallel? It was absurd. They were in series, and could not be anything else but in series. It was a misleading statement, and it certainly ought not to be put down in the paper. He would leave that paper, however. He had given them a sample of what had been put in it. Now he came to Mr. Crompton's remarks, which he felt ought not to go unchallenged. What was the basis of Mr. Crompton's position? It was, firstly, that you must distribute something under 500 volts. Why did he not take 5,000 or 10,000? For a very good reason, because his dynamos would not do it. With 2,000 volts on an ordinary Gramme commutator, made of parallel metal bars insulated with mica, how many years would it last? They had got to find some other commutator arrangement if they were to work at 5,000. He did not say that there were not such machines.

Digitized by Google

Mr. GORDON: What about the Brush machines?

Prof. S. THOMPSON: They had not a commutator of the same kind. Then there were the Thomson-Houston machines. They had not a commutator of the Gramme kind, nor would any constant-current machines that would work with anything like 2,000, 3,000, or 5,000 volts. There was a second assumption underlying Mr. Crompton's whole argument, which was that alternate-current dynamos were necessarily bad as compared with continuous ones, because they required so much room and were very wasteful and would not work in parallel. He was afraid Mr. Crompton was not up to the latest in alternate-current machines, because he happened to know that there were alternate-current machines—they might hear about them, perhaps, in that room before many months were over—that were just as much better than the alternate-current machines already known as were the continuous-current machines of the present day compared with those of five years ago. As to machines not working in parallel, they had indications enough in that room, both from Mr. Mordey and other gentlemen, as to how such things might be done. Put into the circuit of the two machines that are to be synchronised two coils, and let those two coils act as one another, like Prof. Perry's two coils; as long as there was a similarity of phase, they would have an action between those two coils; directly they got difference of phase the action of those two would cease. The motion of the two coils might then be caused to work an automatic regulator. But there were other ways of doing it which he supposed had not been worked out because there had not been until now this great demand. As to the sine curve, he had pointed out, on more than one occasion, that the question of what curves they got for the wave of induction was merely a question of the shape of the pole-pieces. It was perfectly true that the self-induction current acted as a harmonic fly-wheel to flatten down the ripples, and tended to make the form of the wave approximate more nearly to that of its principal harmonic period. He did not think, with all due deference to Mr. Esson's curve, that the machine that gave such a curve was well designed. If it was really a curve of induction, it was perfectly clear that the pole-pieces might have been better shaped. He should wish finally to say that he had no great liking for the alternate current. If he had differed from Mr. Crompton that night, it was not because he did not think that storage in itself—in the abstract—was a great deal better, but he did not at this stage of things want to see any unnecessary difficulties put in the way of the fullest and most complete trial being given to the system of distributing light by transformers. Lastly, he was very sorry that they had not heard that night, or in any previous night's discussion, any mention made of continuous-current transformers of the kind known sometimes as motor dynamos. They appeared to him to be a real success. He was sorry that they had not some contribution from Messrs. Paris and Scott to show how they had been carried out. They knew very little about those machines. When they were doing their work properly the currents in the incoming coil on the armature and the outgoing coil neutralised one another's self-induction. There was a mutual induction between the two, and as a result here, as in the alternate-current transformers, the self-inductions of the two separate coils were practically wiped out by the mutual induction between the two. The consequence was that these machines hardly sparked at all when they were doing full work. It was clear that for all purposes of distribution transformers were the order of the day, whether by alternate currents on the one hand, or by accumulators, or in the third case by motor dynamos. It was clear that they had to study this question of transformation in all its bearings for the basis of immediate distribution.

Mr. KENT asked Mr. Mackenzie to explain the passage in his paper in which he said the "secondary circuit"—that was, he supposed, the "current"—varied directly with the square of the current in the primary. He thought that was not the case. As regarded his device for shielding the secondary circuit from the primary, perhaps he had better explain that this shield is not a bare copper band connected to earth inviting the primary to leak into it, but a heavily insulated band, and so arranged with respect to the two coils that should there be any *tendency* on the part of the primary to leak, it would leak into the shield before it got to the secondary coil. Suppose such a leak does take place, what happens? Why, if there is any other leak on the circuit, an excessive current flows through the two leaky transformers, the cut-outs melt, and the transformers are cut out of circuit. Next, suppose the primary leaks into the shield and also into the secondary—well, then we only arrive at Prof. Ayrton's suggestion of earthing the secondary, and yet he thinks his plan simpler! He considered the practice of earthing the secondary would be very reprehensible. As regards supplementary devices, he had sketched out several to be inserted in the earth wire—that is, between the shield and the earth, some of which might be made to indicate a leak, or ring an alarm if a leak occurred. Coming now to Mr. Kapp's paper, he did not at all agree with him as regards series working. He thoroughly endorsed all Mr. Bernstein had said on the subject. There are three distinct ways of obtaining self-regulation when the primary coils of the transformers are in series.

1st. By putting all the lamps in series on Mr. Bernstein's system.

2nd. By the use of what have been called our "choking" coils, or what we prefer to call "impedance" coils.

3rd. By building up the transformer in sections so far as the core of the secondary is concerned, and connecting each lamp or group of lamps to its separate section.

The first and third of these methods is admirable for small or medium-sized transformers, and the third will do for any size All three are perfectly self regulating. As the second method has been described elsewhere, we would not take up your time with it here. From their experiments they had found that an induction of 5,000 is quite high enough for satisfactory working.

Mr. KAPP, in reply, said that in the first place he would answer Prof. Silvanus Thompson as to the difference between the core transformer and the shell transformer. The shell transformer had one set of coils and two cores or more. A core transformer had one core and two sets of coils or more. Now, as to Mr. Wright's contention that the shell transformer was superior. He quite agreed with that gentleman, and that was the reason why he made *his* a shell transformer. He did not say the Zipernowski was superior, he said it was inferior. It was a shell transformer of a circular ring type. It might interest Mr. Wright to know that what he (Mr. Kapp) arrived at through calculations Zipernowski had found out by experiment. He had abandoned the Zipernowski type of transformer and now made ordinary Gramme rings.

Mr. Mordey suggested a very interesting experiment. The angle of lag in one or two of his (Mr. Kapp's) diagrams was so small that the cosines had such values as ·999; so that they might imagine they could not get an appreciable difference in the readings. Probably there was a difference, but the error of the measuring instrument was greater than the difference.

As to the cost of the network, he objected to putting transformers into houses simply on the ground of safety, and he thought whatever they did that they must study the safety of their customers before the coal bill and before any other consideration. As long as they had transformers in the houses they were not safe. Children would put their hands on the terminals and accidents would happen. When they put the transformers outside they had the other advantage, that if one transformer broke down the houses in the immediate neighbourhood were not in utter darkness, because the other transformers would supply a little more and it would flow through the network to those houses. They were bound to have a network, and instead of having such enormous mains as Prof. Forbes brought before the society some time ago they would have mains with a very small section, with transformers every fifty yards. The mains would be exceedingly small, and need not cost more than Mr. Crompton's mains. If they adopted the principle of distributing the secondary currents by means of a proper network, once they had laid it down, they could use it when that happy time arrived when they could employ the battery system. Mr. Esson asked a question about the weight of transformers. This depended entirely on the size. Some of the transformers exhibited weighed a pound and a-half for every lamp. The small transformer that Prof. Ayrton tested weighed two pounds to every lamp. One and a-half pound for a lamp would be the average for medium sizes.

He would now deal with Mr. Gordon and Mr. Crompton. When he heard those two gentlemen speak he began to feel very doubtful whether after all they were not all of them going on a wrong line; but then he was comforted with the idea that supposing even such a man as Edison, or Brush, or Westinghouse had been present, and had seen Mr. Gordon's diagram, he would have gone home disheartened, and resolved never to put up a central station again because of the enormous consumption of current when the people had gone to dress for dinner. But what was the fact? How many battery stations were there in the world? He knew of absolutely only one in London, one in Berlin, and one in Vienna. How many central stations on other systems were at work he was afraid to say, but he thought in America there were something like 1,000. On the Continent of Europe there were perhaps 100 or 150. In England there were, perhaps, fifteen. All these were working on the direct system, and their machinery must be capable of supplying this extra spurt shown on the diagram. But that was a bad case. In reality they could only have that effect when they lighted the same class of houses throughout a district; but in London they never had a district so defined. They had residential mansions, and within a stone's throw they had mews and shops, all within the area which would be supplied from one station. That being the case, they would never have to meet such a state of things as Mr. Gordon suggested. If they had to meet it all they would have to do would be to make some allowance in their machinery. In what way was Mr. Crompton better off than they were? He had to supply this extra amount of light from the batteries instead of from the machines. They would have to put up more cells, and it was the battery which cost the money, not the engines. He was not against batteries in any way. He would hail the day when they could get a good battery, but all the arguments used by Mr. Crompton and Mr. Gordon might have been used with equal consistency three years ago. They had batteries then, and they had very good direct-acting steam engines and dynamos. Had they good enough batteries now? He had not seen them. The batteries which were at the Colonial Exhibition gave an efficiency of under 60 per cent. They were in the hands of experts. Everything was done that could be done. They were under supervision all day long, and yet there was only 60 per cent. efficiency. When it was said that transformers were bad because they had a low efficiency when the output was very small, they must remember that they could work up to 90 per cent. efficiency at a moderate output, and 96 per cent. at full output. He maintained if they put down a network of mains and employed transformers to feed them, no transformer need work at less than a third of its output (where its efficiency was 85 per cent.), for the simple reason that when the output got less they could cut off a feeder and let the network be fed from the others. The point about the dynamos in parallels had already been answered, and that finished the whole argument about the big machines necessary for doing the work. What they would have would be three or four engines, and if they wanted to use a quarter of the power they would use one engine, and if they wanted full power they would let all four of them run.

He would now like to say one word about the question of dynamos. He thought they would go away frightened at the size of the alternate-current machines if they took Mr. Gordon's figures, who spoke of a machine giving 200 kilo-watts, with an armature 10ft. in diameter. Now, the machine which was shown last Thursday on the board was of 60 kilo-watts, and the armature was 40in. diameter. If they built a machine on the

Digitized by Google

same lines with a 6ft. armature it would give them 200 kilo-watts, and the machines would weigh about 80lb. per horse-power, which was less than a continuous-current machine.

He would now deal with the discussion of last Thursday. The calorimeter experiments of Prof. Ayrton he thought were very interesting, and, as far as he knew, they were the first exact experiments that had been made. There was one point, however, when experiments of that kind were made to which attention should be given. That was the temperature of the room in which the calorimeter was placed. They should have the mean temperature between the incoming and issuing stream of water about the same as the temperature of the room. That they could always do because they could regulate the flow. Suppose that their room was 15deg. C., if the incoming water was 10deg. C., they could regulate the flow so that the outcoming water should be 20deg. C. Then the mean temperature of the calorimeter would be 20deg. C., and there would be no flow of heat from the air of the room to the calorimeter.

Prof. Ayrton said that this precaution had been adopted.

Mr. Kapp: Several speakers that night and also on Thursday spoke about magnetic lag. He would be a bold man who said whether there was or there was not, because nobody had proved it; but he thought there was not, and his reason for so thinking was that if there were lag he could not see how any telephone could articulate. If there were lag, the lower the voice going through the telephone the better they ought to hear. Now, as a matter of fact, they heard a high voice better than a low voice. The high voices have quick waves, and should be more distorted by lag, but they were not more distorted, and for this reason he was inclined to think that there was no lag, and until somebody showed him actually by experiments that that opinion was wrong he should hold it. Captain Cardew and Mr. Bernstein had objected to the safety device which he put between the two coils, and Mr. Bernstein had characterised it as leading the primary current into temptation. Now, what was this temptation? It consisted of the presence of metal outside the primary current, but between this metal and the coil there was insulation. In what did this differ from the temptation which existed in every transformer? They had the metal in the secondary coils, and they had insulation between them and the primary. With the core itself it was just the same thing. And in what way was the strain brought on the insulation of the primary greater on account of this shield, as compared with the strain which was already brought on it by the presence of the core? They were bound to have iron somewhere, and whether they had it in the inside only or on the inside and outside as well, the strain on the insulation was the same. So that he believed the objection was merely a sentimental one.

Mr. Bernstein had asked a very interesting question—which was the most effective at the lowest output, a series or parallel transformer? That depended on the ratio between the loss taking place in the iron and in the copper. When they worked in parallel the magnetisation was a constant. Therefore, the heat generated in the iron was a constant for all loads. When they worked in series the magnetisation of the iron was very little when the work was little. But as to the heat generated in the copper, this was constant. If there were two transformers in which the heat generated in the iron and generated in the copper for full output were equal, then the efficiencies would be also equal for smaller loads. The efficiency would be the same in both cases at a low output, but inasmuch as generally the heat of iron was more than the heat of copper, the series transformer would be slightly better in efficiency for a low output. Dr. Fleming made a suggestion which he was very glad to hear—that was, that experiments should be made on the heating of iron under different rates of alternation. He hoped that some one would provide funds enough to carry out the experiments. Dr. Fleming wanted to try what was the permeability of iron at different periodicities. That would be interesting in itself. But a far more important question would be, what was the heat generated in iron at different degrees of magnetisation and different number of alternations per second? That was the real question. That regulated the design of transformers. If they could only magnetise their core more than they did now, without producing more heat than they did now, they could make transformers which would be exceedingly small for the output.

Referring to the general question of batteries *versus* transformers he wished them to understand that he was at present in favour of the latter, simply because he had no confidence in batteries. If he knew batteries were good enough he would never presume to put down alternating plant; but he had never seen a good battery, and, therefore, that was the only way of doing the work. It was done everywhere. As Mr. Mordey said, they might as well try to stop the sea as try to stop the employment of alternate currents. But in order to provide for the day when batteries would be good enough, they must put their plant down now so that most of it could be used later on. What would they have to throw away, and what could they retain? They could retain their boilers, engines, and stations. They could retain the whole of the network, and the whole of the distributing plant to the houses. What they had to throw away were their alternating dynamos and the transformers. Both together would not cost more than 10s. a lamp. The wiring and fitting of each lamp in a private house would cost at least 30s. to 35s.; the conductors would cost something like 30s. again; so they could see that by introducing alternating currents they would only risk a possible future sacrifice of about 10s. per lamp in an installation costing from £3 to £5 per lamp originally. Nearly the whole of their plant would remain equally serviceable when the day arrived that batteries could be used. Until then they would find the alternate current and transformer system good enough, safe and reliable for all practical requirements. It seemed to him that there really was no fault to find. They did not advocate a thing which was altogether wrong, and which would be altogether wrong in a few years. They advocated a thing which with a very little sacrifice would be good for the day when they had batteries.

Mr. Mackenzie: In reply to Prof. Ayrton's query as to whether the coils he spoke of were ever seriously tried at the Grosvenor Gallery installation, he would only say that some experiments had been made with an apparatus consisting of a single coil of fine wire placed in shunt to the primary of the series transformers then being used, in which coil was inserted, a core formed of a bundle of iron wires, inserted more or less by hand as the output from the secondary of the transformers varied. No good results were, however, obtained, as the coils that were tried invariably got burnt up in course of time. The idea was abandoned, and no further experiments were made, it being decided about that time to put the transformers in parallel. Mr. Bernstein had suggested that his fusible contact plugs would serve as a means of putting the secondaries to earth should the potential rise above what was proper, and he—Mr. Mackenzie—thought that such an arrangement was quite feasible, and would prove cheaper than the apparatus devised by Captain Cardew, which was, however, in itself an excellent and ingenious contrivance; but he objected altogether to putting the secondaries to earth in an installation based on the transformer system, for reasons which were numerous, and had already been mentioned by previous speakers.

Mr. Atkinson, in referring to the Kingdon dynamo, wondered whether Mr. Mackenzie had experienced, in working this machine, a large amount of alternation in the exciting circuit; and this effect had in reality been observed, though not to any great extent, and was probably due to the causes mentioned by Mr. Atkinson. Mr. Kingdon, in stating that the fly-wheel of an engine would form part of his machine, did not intend to convey the impression that existing engines were preferably to be so altered; but that in designing a dynamo for a central station, the fly-wheel of the engine, necessary in any case to ensure steady running, would be made to form part of the dynamo, and thus combine two functions in one. The object of arranging the machines into various circuits so as to admit of alterations in the coupling was obvious, since bobbins could be cut out of circuit as the output diminished, thus working the remainder at their maximum. There were many reasons why it would be advantageous to be able to alter the connections of the bobbins, but the want of time prevented him going into the matter.

In answering Mr. Crompton's request to give him information regarding the efficiency of the transformer system, he thought that Mr. Crompton was at present asking for rather too much. Regarding the saving of copper used by the employment of this system, reference to the diagram on the wall would make this clear, and he thought that many of the objections that had been raised by Mr. Crompton had been met and successfully answered by several speakers that evening. There would be no gainsaying the fact that the transformer system had made tremendous way, and this would never have been the case had not the system possessed merits placing it before all others for the general distribution of electricity. He quite expected to see Mr. Crompton, before very long, becoming as warm an advocate of the transformer system as he had, not many years ago, been an opponent of electrical distribution by secondary batteries.

Mr. Gordon had gone very fully into the relative merits of the two systems, but he had been answered by several gentlemen who had joined in the discussion that evening, and the speaker was afraid he could not altogether agree with the conclusions Mr. Gordon had arrived at.

Prof. Silvanus Thompson, as well as Mr. Mordey and Mr. Madgen, had called attention to his statement on page 1, regarding the Faradaic theory. He wished to point out that the words, "*and* exemplified by Ruhmkorff," should be "*as* exemplified by Ruhmkorff," M. Gaulard never having dreamt of denying the Faradaic theory of induction, as such would have been absurd on the face of it; but he distinctly laid down the dictum that the Ruhmkorff coil, more or less modified, formed the basis upon which all previous experimenters had worked, and had consequently been utterly unsuccessful. Regarding Mr. Madgen's mention of Jablochkoff, he denied that that electrician had ever conceived the idea of a transformer system as now existed. He quite recollected the apparatus exhibited by M. Jablochkoff, in Paris, at the Great International Electric Exposition of 1881, but that system then shown at work as a "transformer system" was no more—either theoretically or practically—like what Gaulard had discovered, than a Wimshurst machine was like a dynamo, and he did not think the subject worth discussion.

Prof. Thompson had objected to his statement that when one transformer only was connected to a dynamo it was "either in parallel or series;" but he did not see how anyone would prove the contrary, in spite of the argument brought forward by the Professor, since, like a "quarrel," it took more than *one* to make a parallel or series circuit.

Seeing the hour was so late, he was unable to say more in answer to the remarks made by the numerous gentlemen who had joined in the discussion.

The President said that votes of thanks had already been given to the authors of the papers, and, considering the extreme lateness of the hour, he could only say they were very much obliged to those gentlemen for having called their attention to a subject the importance of which could not be exaggerated, and to which their attention had not hitherto been called by any previous writer of a paper. It had given rise to a very interesting discussion, a discussion which had fulfilled the object of most discussions, as it had brought out a great divergence of opinion, from which probably some truth might be hereafter gained.

The proceedings then terminated.

Captain Cardew has been good enough to send us a copy of the curves (Fig. 7) which he has drawn to represent effective exciting power and magnetisation, and to which he referred in his remarks during the discussion on Mr. Kapp's paper, as reported in our last issue. Captain Cardew writes:—"Doddington House, Strood, Kent,

Digitized by Google

26th Feb., 1888. I send you my idea of curve representing magnetisation in relation to that representing effective exciting power in a transformer. This is merely an illustration of what I meant at the discussion and not in any way derived from experiment. The curve of effective exciting power is assumed to be sinusoidal. The curve shows the probable lag during magnetisation recovered during demagnetisation, and the sluggishness under weak force due to hysteresis or molecular friction. Of course the magnetisation is supposed to be always far below saturation."

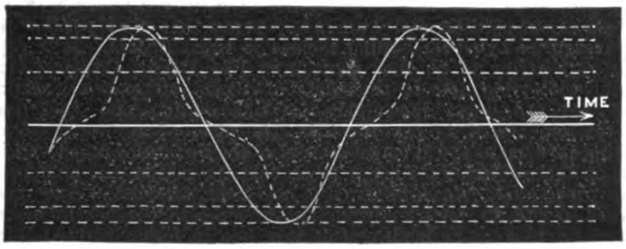

FIG. 7.

Effective exciting power, firm line. Magnetisation, dotted line.

The dotted lines left at 0·5", 0·866", and 1" (sines 30°, 60°, and 90°) show how the sinusoidal curve is drawn, and laying off a scale of ¼" along neutral line in drawing ordinates. The other curve is drawn by eye.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

2,772. K. W. HEDGES. London. Improvements in electrical safety appliances. February 24, 1888.

2,784. J. IMRAY. London. A method of and apparatus for electrically lighting railway and other carriages. (R. Imray, South Australia.)

2,785. E. F. H. H. LAUCKERT. London. Improvements in holders for electric glow lamps. February 24, 1888.

2,794. C. A. M'EVOY. Southwark. Improvements in electrical firing keys or contact makers. February 24, 1888.

2,808. H. F. JOEL. London. Electro-magnetic conductors for electric and magnetic machines, induction coils, transformers, &c. February 25, 1888.

SPECIFICATIONS PUBLISHED DURING THE WEEK.

3,225, 1887.—R. DICK and R. KENNEDY. Generating and distributing electric energy, &c. (Price 8d.)

4,032, 1887.—M. IMMISCH. Holder for brushes of electro-motors, &c. (Price 8d.)

4,322, 1887.—J. and E. HOPKINSON. Dynamo electric machines. (Price 11d.)

4,472, 1887.—S. P. THOMPSON. Electro-deposition of cobalt. (Price 6d.)

4,978, 1887.—F. T. SCHMIDT. Holder and switch for electric lamps. (Price 8d.)

4,980, 1887.—F. T. SCHMIDT. Making and breaking electrical circuits. (Price 8d.)

5,009, 1887.—J. T. ARMSTRONG. Secondary batteries. (Price 6d.)

5,092, 1887.—B. EGGER. Switches for electrical purposes. (Price 8d).

5,228, 1887.—W. H. BAYLEY. Holders for incandescent electric lamps. (Price 8d.)

5,707, 1887.—E. F. H. H. LAUCKERT and H. W. KINGSTON. Automatic cut-outs for electric arc lamps. (Price 8d.)

6,972, 1887.—J. C. MEWBURN (La Société Anonyme pour la Transmission de la Force par l'Electricité). Obtaining derived currents of variable intensity from a main electric current. (Price 8d.)

COMPANIES' MEETINGS.

The Anglo-American Brush Electric Light Corporation (Limited).

The seventh ordinary general meeting of this Corporation was held at the Cannon-street Hotel, on the 2nd inst., the Right Hon. Lord Thurlow, F.R.S., presiding.

The SECRETARY (Mr. E. Garcke) read the notice convening the meeting.

The CHAIRMAN, in the course of his remarks in moving the adoption of the report, said : I think you will concur that all that has happened, if not everything in connection with our industry during the past year, has been entirely satisfactory to your interests, and it has convinced me very fully that the affairs of this Corporation rest upon a sound financial and commercial basis. We have now worked at a profit during the whole of 1886-7. During the last twelve months the volume of our business has increased by 23 per cent. over what it was in 1886, and during the same time, owing to economies we have been able to introduce, our net profits have increased by nearly 10 per cent. That I think is a very favourable state of affairs taken by itself, but it is more satisfactory when it is considered by the side of the great fall that has taken place in the prices of electrical appliances of all descriptions. The result of the year's working is to show a respectable balance. We think, however, that we should not be paying due regard to the permanent interests involved if we adopted the course of paying you what I cannot help myself considering as a small dividend. We think it is wiser to keep the money in our pockets in view of the great development we anticipate to take place in the course of the next 12 months in electric lighting generally. We

Digitized by Google

therefore hope you will adopt the scheme, which you will find in our appropriation account, of putting £2,500 to what is called provision account, and carrying £2,500 to the account of this year.

Before I go further, however, I wish to say one word on the depreciation of prices in order to bring home to you to what an extent this has occurred, and how greatly it has increased our difficulties. In 1881 the largest class of Brush dynamo we made cost £800. We now make a machine more efficient, more powerful, superior in manufacture, better in every conceivable way for £360, or less than half, and it is only by getting down from £800 to £360 and making a better and more efficient machine that we are enabled at all to compete with other makers. As regards economies we have been aided by our very efficient staff, and thus we have been able to counterbalance this depreciation. I may explain in a few words in what departments those economies have been effected.

First of all we have succeeded at length, after attempting to do so for two or three years, in bringing all our manufacturing processes and all our work under one roof at Belvedere-road, Lambeth. We have been enabled to do that by sub-letting the works in the Borough-road, and by, on favourable terms, renouncing the lease of our works in Portpool-lane. In the second place, we have been enabled to introduce economies by making more favourable contracts for coal, oil, and other things. A third economy we have been able to introduce was foreshadowed in our last report—I refer to the arrangement that has been carried out very efficiently by the negotiations which have been conducted by our assistant secretary, Mr. Fells, with the various railway companies for a reclassification of their rates for the transit of electrical machinery. I have two diagrams which will convey at a glance our position. The first is a little diagram prepared by our ever active secretary, Mr. Garcke; it shows you the upward tendency of our business from 1883 to 1887. The other diagram is a little more complex, but it is no less satisfactory and interesting. It shows the fluctuations in the general charges and the gross profits during the years from 1883 to 1887. Comparing this diagram with the other it will be seen that in 1884 the expenses of management fell from £21,700 to £14,700, concurrently with the increase of business; that in 1885 the expenses rose slighly, but that the business and profits rose in a much higher degree; that in 1886 the expenses fell from £15,800 to £13,800, though unfortunately the volume of business also fell; and that in 1887 the three factors showed an improvement, the expenses being lower than ever, the profits having increased from £13,000 to £16,000, and the volume of business extending to upwards of 50 per cent. as compared with 1886. I think these are figures which any commercial company may point to with pride, especially at a moment like this, when it is almost doubtful whether there is any active recovery of trade.

You may very reasonably desire to have some information respecting our Continental or Austrian business. You are aware how we acquired that business. It was the result of absorbing the International Company, which was really the Anglo-Austrian Company. We absorbed that company last year on favourable terms. We obtained possession of all their assets on terms which you approved at the time, and certainly which I do not think you have had since any occasion to regret. These assets, among others, consist chiefly of two things—the street-lighting installation at Temesvar in Hungary, and the share the International Company held in the firm of Kremenezky, Mayer and Co., electrical engineers and manufacturers, in Vienna. Temesvar really consists of three towns all joined together, and the streets are now entirely lighted by electricity, and have been for some years. It is lighted by mains over thirty miles in length in the streets of the three towns. It is lighted exclusively on the Brush system, and has been in successful operation since 1883. The contract with the municipality is a very favourable one to the undertakers in many respects. The term of the contract is twenty-five years, and at the expiration of that period the municipality can either renew the contract or purchase the works from us at a fair valuation. The lighting of the streets is effected by 700 incandescent lamps. When the Corporation took over that installation it was not quite self-supporting, owing to the expensive manner in which some of the details were managed. Since we have had charge of it, we have appointed a new manager, a very admirable man, Mr. Clements, and he has fully justified the authority that we gave him to deal with matters at first hand. I am happy to be able to inform you that the private lighting along those 30 miles of streets is now almost daily on the increase and is giving great satisfaction, and instead of being conducted at a loss, that installation is now being run at a small profit, but a monthly increasing profit. It also affords what is satisfactory to be able to point to in the present day—an instance of a whole town having adopted the electric light in preference to gas, which was formerly there. The business of Kremenezky, Mayer and Company we have now obtained entire possession of. We paid for the remaining portion of the business a reasonable sum down in cash, and we made an arrangement with Mr. Kremenezky, who is a man of very great energy, to continue the management of the business. The business is an increasing one. It has before it a great field, and I believe substantial profits. The only point I regret about it is that it is essential from time to time that an officer of the Corporation at home should go out to Vienna and see that everything is going on properly. I regret greatly this, because it has deprvied us during the year for a time of the services of Mr. Garcke, whose acquaintance with Germany and the German language has proved invaluable on this occasion. As regards the accounts for the past year of the Austro-Hungarian business, they were not received by us in time to be included in our balance-sheet, but they have since come to hand. An examination having been made of them, there is a profit on the business of the past twelve months.

The report alludes, among other things, to a matter of interest, namely, the largest arc light installation ever done in England—that of the Manchester Jubilee Exhibition last year. It consisted of 600 lamps, which were exclusively on the Brush system. It ran for six months, and it gave satisfaction to all concern. We ran the risk of heavy penalties in connection with that undertaking, and I am happy to be able to tell you that we were not called upon to pay a shilling fine, and at the termination of our contract we received letters from the authorities and the exhibition people congratulating us on the manner in which we had performed the work. We have now undertaken a similar piece of lighting, but of 400 lamps instead of 600, for the Glasgow Exhibition, and I feel confident that we shall give satisfaction there equal to that which we gave at Manchester.

I now come to a subject of great importance, which is known as compound winding, for which we hold exclusive patents. There was some litigation going on last year on this subject. We have every confidence in the strength of our position, and I am happy to say that that position has been recognised by all the leading makers in Great Britain. It is especially satisfactory to us that great firms like Messrs. Crompton, and others, while they felt it their duty of course to oppose our claims, have behaved most honourably in this matter, and they took licences and agreed to pay royalties. In place of any soreness now existing between us and them on account of the threatened litigation with them on that subject, I am happy to say that the matter has brought us nearer together. We consider that we have established our position in regard to compound-winding machines in Great Britain, and that no machine can be made on this principle in future without being subject to a moderate royalty to us. There is only one firm that contests our right. We do not regard their action as of any importance.

There are subjects of technical importance to which the attention of our staff has been directed during the past year. Electric science, as you know, has not yet reached perfection or maturity. It is necessary to follow the progress made in the laboratory very closely in order to keep in the forefront of manufacturers of this class of goods. It is for this reason that you will find in our account every year a sum devoted to what we call developments of various patents and further improvements and inventions, without which we should fall into the background. We are now making alternate-current machines under an entirely new design. We have also patented a new type of transformer for transferring high tension into low-tension currents, and *vice versâ*.

We have introduced into our establishment a bonus scheme for admitting the principal officers of our staff and the heads of departments to a participation in our profits. We did not adopt a scheme of that kind without much consideration. It is nothing new; it has been adopted by very many of the largest firms in the kingdom, and successfully adopted. We feel that it is the right principle, and we have, after mature consideration, adopted it subject to your approval. The deduction that it will entail from your profits is more nominal than real, for we have proved to our satisfaction that it does not amount to a deduction from your profits but to a small percentage of the economies effected, which go into the pockets of those persons through whose instrumentality alone we can effect these economies.

I should now like to draw your attention to a few figures which are very striking in the balance-sheet. In connection with the first item on the credit side of the balance-sheet I do not wish to shirk the least responsibility. I refer to the figure at which our patents now stand, £57,674. I am bound to say that, knowing what these patents cover, I consider that that figure is an eminently satisfactory one, one that I can regard with the most perfect equanimity. You must remember that in 1882 your patents stood at £179,468, and since then they have been written down to £57,674. And not only that, but you must remember that we have acquired the Brush licenses for the metropolis, for the provinces, for the Continent, and for British India, with the exception of Hyderabad and Bombay. In addition to that we have acquired new patents, to some of which I have referred, and our patents are more valuable than in 1882, while they stand at between a third and a fourth of the amount. The next figure is the item of our property, £82,737. That is a figure that will also bear any examination, representing, as it does, property which, if it were realised not suddenly but with common prudence, would give you a very good return for the figure at which it now stands. You must also bear in mind that there is provision made for any shortcomings to the extent of £14,000, which amount, if you adopt this balance-sheet, will be increased to £16,500. Then I come to the question of debtors and creditors. Last year we owed our tradesmen on current account £12,848; this year, notwithstanding that we are doing more work, that our establishments are much more busy, and that our contracts are much heavier, we owe our tradesmen less by £500. On the other hand, the money due to us, which is all good, was last year £30,600, and this year it is £45,600, or 50 per cent. more.

There is now a point I must refer to which I had hoped General Webber would have been here to speak on to-day—the City lighting. As you know, the negotiations we have been conducting with the Commissioners of Sewers have been pending for several years. We have been going on patiently, and we have met the Commissioners of Sewers with every attention. The negotiations are not, I am sorry to say, sufficiently complete to enable me to tell you that they are final, but, at the same time, I have every conviction in my own mind that after the length of time these negotiations have been going on and from the close point at which we have now got them, there can be but one result from them, which is acceptance of our offer. Under that contract we should have to deposit £1,000 in the first instance, which we are to forfeit entirely if we do not begin to work within a very few months after the signing of the contract. Sufficient guarantees are also placed in the hands of the Commissioners of Sewers to completely cover any risk that may be run from any undue temporary monopoly we may acquire under the contract with them for the private lighting. In fact, the Commissioners of Sewers very properly have seen fit to surround the contract that is to be given to us or someone else with every conceivable precaution in the interests of the public. If we get that contract we shall do our utmost, and I feel confident we shall succeed, to execute it satisfactorily. But it will not be a contract

Digitized by Google

from which directly we shall obtain enormous profits, or, in fact, anything more than the fair and reasonable tradesman's profits. That is my view of it. Indirectly, of course, it would benefit us. We have within the last few days received letters addressed to us spontaneously by some of the largest firms in Great Britain expressing their sympathy with us at the wearying delays connected with these negotiations, and hoping that they may not be much longer protracted, as they are so detrimental to the electric lighting industry generally.

The noble Chairman then referred to the Bill pending in Parliament promoted by the South Eastern Railway Company, one of the powers sought by which measure being to acquire the premises of the Corporation, or part of them, in Belvedere-road, Lambeth. He stated that after great difficulty they had at length got their works and business concentrated under one roof, and they must be subjected to inconvenience whatever portion of their premises might be required to be taken by the railway company. The Corporation were not exacting in their demands, and he believed they would bring the railway authorities to a sense of the justice of their demands for reasonable compensation for taking their premises, or any part of them.

Speaking of the litigation with the Edison and Swan Company he continued: I did not intend to say a single word on this subject, for I am one of those who accept the doctrine that there is an unwritten law and very proper custom not to discuss any matter of this kind that is actually before the Courts. I do not think that it is right to do so. As, however, that view of the case was not taken the other day by Mr. Forbes when he addressed his shareholders at the Swan meeting, I hope you will pardon me if I also ask your permission to say a few words. I have not a word to say against what fell from the lips of Mr. Forbes as regards ourselves. He spoke courteously, I am told, of the Corporation, and especially went out of his way to say that the term "rascally infringers," of which he had made use, was not intended to apply to us, and that he did recognise that we possessed certain patents. Well, that is very good of him, and I think no one knows better than Mr. Forbes that we do possess patents. I desire to assure you that if this matter has gone into court, and is to be decided by the Court, it is owing to no fault of ours. We have approached Mr. Forbes's company at different times, and made every proposal to him that we felt we could properly make as the custodians of your patents, rights, and interests. If an arrangement has not been come to, I cannot admit for a moment that it is owing to any neglect on our part of what we might reasonably be expected to have done in this matter. We are advised by our counsel and by some of the greatest experts and most powerful technical minds in the country that we have not only a good case, but an overwhelmingly strong case. We are armed at all points, and are ready for the fray. We face the position forced on us not only with equanimity but with perfect satisfaction and confidence. Whatever the result of this litigation may be it can hardly fail, if thrashed out in the courts of law, to weaken or completely break down those bars for some years to come to the flood of unscrupulous and ignorant promoters to which at present the free trade in electric lighting would and inevitably must expose the ordinary householder. Finally, you must remember that this action, be the result whatever it may to us, affects only one portion of our business; while to the Edison and Swan Company defeat probably means ruin.

Before I sit down I desire to take this opportunity to thank one of the best known men in the City, the able and indefatigable secretary of the Stock Exchange, Mr. Burdett, for sending to me, as he courteously did, a copy of his invaluable work, "The Official Intelligence for 1888," and I wish to draw your attention to one of the introductory chapters in this year's volume, on the early history of gas lighting, for you find detailed the difficulties gas lighting met with at its introduction in the early years of the century. You will find reference made to the hopeless struggle which the introducers of the gas industry met with for fifteen or twenty years. How hopeless it seemed at that time can only be gathered from reading these pages, and that was even in the absence of the legislative restrictions to which we are exposed. The promoters of the gas industry found that it took twenty-five years before they could work at a profit, and even then it was only by the original shareholders two or three times sinking and absolutely losing every farthing they had invested in the undertaking. I know as much as most people how much money has been lost in introducing the electric light, but I am thankful to say that by the study of these pages you will find that not a fourth of the money has been lost, sunk, or thrown away on the introduction of the electric light compared with what was sunk, lost, or thrown away in introducing gas light; and so far from taking twenty-five years to make it pay, I do not like to prophesy, but I venture to say that from twelve years from the introduction of the science, in 1880, there will not be a gas lamp in the streets of any town in England. He concluded by moving the adoption of the report and accounts.

The Vice-Chairman (Mr. J. S. Sellon) seconded the resolution, and briefly alluded to the rapid progress of electric lighting in America, and the encouragement it should afford to those engaged in the same work on this side.

Mr. Hart inquired whether arrangements had been made to take other premises in the event of the railway company wanting the works. In regard to the litigation between the Company and the Edison and Swan Company, were not the Company in the position taken up by Messrs. Woodhouse and Rawson in the late actions between that firm and the Edison and Swan Company? The number of the Directors was less, but he noticed that the fees were the same—£1,500—which he thought rather heavy, seeing that the Company were not paying a dividend.

Mr. Weir, as an original shareholder, expressed satisfaction at the progress which had been made. The chairman had predicted that in twelve years from 1880 every street lamp in England would be lighted with electricity and not gas, but the gas companies admitted that the street lighting was not very profitable to them. What was wanted was to get the domestic lighting. He was glad to gather that the litigation was not so serious as one would imagine from reading the speech made by Mr. Forbes the other day. He thought that the stock on hand was rather too large. He quite understood the view of the Chairman that every shareholder in electric light companies should read the article referred to in Burdett's "Official Intelligence."

Mr. Stobart thought that it would be advantageous if there were one or two commercial men on the Board, which he noticed was composed almost entirely of scientific men.

The Chairman, in reply, repeated that the subject of a possible removal to other premises was receiving careful consideration and attention, but they could not commit themselves to taking new premises until they were turned out of their present buildings. It was uncertain what portion of their premises the railway company wanted. As regards the litigation, he would ask Mr. Renshaw to say a few words, following the example of Mr. Forbes at his meeting, in desiring Mr. Crisp to address his shareholders.

Mr. Renshaw said he quite agreed with Lord Thurlow that it was not desirable to discuss a matter as to which litigation was pending; but as for the reason stated by his lordship he had been called on to address them, he might point out the exact position of the litigation. He might first state that the Brush Corporation did not seek the litigation, which was forced on them by the Edison and Swan Company. The Company then looked at their own patents and discovered that every Edison lamp made by the other company infringed one of the Brush Company's patents, and that every Edison lamp used in connection with storage batteries infringed another of the Brush Company's patents, the Lane-Fox. They commenced a cross action against the Edison and Swan Company, respecting which they had been assured by the most competent counsel and the most able experts that they would succeed. With reference to the action of the Edison and Swan Company against the Brush Corporation with respect to the lamp, it was practically re-trying the case of Woodhouse and Rawson, but it was re-trying it with fresh evidence, which made them feel sure as to the Edison patent, and with respect to the Cheeseborough patent they also felt that they would have perfect success.

The Chairman then put the motion and it was carried unanimously, the retiring Directors and auditors being subsequently re-elected.

On the motion of Mr. Weir a hearty vote of thanks was passed to the Chairman and Directors.

The Telephone Company of Egypt (Limited).

The fifth ordinary annual general meeting of this Company was held at the offices, Austinfriars, last Tuesday, under the presidency of General Alexander Fraser, C.B., R.E.

The Secretary (Mr. Alexander B. Chalmers) read the notice convening the meeting, and the report of the Directors was taken as read.

The Chairman said: I think that as shareholders we may look upon the position of our Company at present as being favourable. Starting in 1883, we paid for the first year 2½ per cent. on the preference shares; in 1884 we paid 3 per cent., in 1885 5 per cent., in 1886 6 per cent., and now, for the last year, we propose a similar dividend. After writing off a considerable sum for depreciation we carry forward an amount practically equal to about 1 per cent. on the preference share capital. Our gross business has increased by quite 50 per cent. since we started, and I am glad to say that our working expenses have not increased in anything like the same proportion. For this happy feature in our business—that is, the economical working—we were greatly indebted to the late manager, Mr. A. D. Evans, whose death in our report we very much deplore. We have appointed his son, Mr. W. N. Evans, to be the manager of our business in Egypt. We thought if we could, compatibly with the interests of the Company, appoint Mr. Evans' son to the management of the business, it would be a fitting tribute to the excellence of his father. We made due inquiry in the matter. He was strongly recommended by the leading merchants and bankers in Egypt. He had been under the tuition of his father for some time, and the chief agent in India of the Oriental Telephone Company being on his return to that country, we asked him to report on the general management by this young man. I am happy to say that this report was very favourable. Under those circumstances we had no hesitation in appointing Mr. W. N. Evans in place of his father to the management of the business in Egypt. However, Mr. W. N. Evans is a very young man, and we took advantage of the offer of three gentlemen in Egypt of first-rate position, who volunteered their services to form themselves into a committee to discuss matters of importance with the manager. Those gentlemen have formed themselves into that committee, and we anticipate successful management through this arrangement. We are glad to report that, so far, our new manager gives evidence of that cautious and economical management which was so distinctly shown by his father. I am glad to be able to state that since we made our report the extension of our business to Helouan, which is about sixteen miles from Cairo, has been completed, and we expect a large business from that connection. You are aware that there is considerable competition in Egypt in all business, and it is necessary that we should provide means by working capital whereby we may be able to utilise the concessions which we have obtained from the Government, and after consulting our principal shareholders we came to the determination to ask you to pass a resolution to-day to extend our borrowing powers from £5,000, as at present limited, to £20,000, and we propose to create debentures to that amount, of which we intend a present issue of £10,000 only. Of this sum a portion will be required to pay off a loan that we have from the Oriental Telephone Company and the remainder will represent the working capital of the Company. It would not be consonant with good

Digitized by Google

policy to let any chance slip of increasing our business by reason of any delay in having to ask you for the means to carry out any extension of our business, and it might not prove convenient to the Oriental Company to continue the loans, from which we have hitherto derived great benefit at a moderate interest. You will observe that, including the above loan now to be paid off, we have spent about £10,000 on new constructions over and above the capital issued for the acquisition of the business as a going concern, and as this total value now represents £70,000, on which we are earning some 6 per cent., we think with such security the investment in our debentures at 6 per cent. will be undeniably a good one, and we ought not to have any difficulty in placing these debentures. You may, perhaps, ask why we carry forward so large a sum as £665, which represents 1 per cent. on the preference capital; but you will observe that while our gross business has extended some 50 per cent., the mean value of each subscription has decreased, and we have therefore thought it safer to carry forward a substantial sum. The decrease in the rate of subscription, of course, popularises the convenience which the telephonic business represents to business men, and it will be satisfactory if it be more than counteracted by the extension of our system. I do not think that I have anything more to say, but before proposing the resolution I shall be very happy to answer any question. No question being asked, however, he continued: I move—

"*That the report and accounts be received and adopted, and that a* "*dividend of 6 per cent. per annum on the preference shares be paid on* "*13th inst., free of income tax, and to be applied as stated in the report.*"

Mr. HENRY GREWING: I beg to second that.

The CHAIRMAN put the motion in the usual way, and it was carried unanimously. Continuing, he said: Then, in regard to what I said just now with reference to the debentures, I have to move—

"*That, in accordance with Article 60 of the Articles of Association,* "*Sub-section A, the Directors be and they are hereby authorised to raise* "*money by the issue of debentures to an amount not exceeding £20,000.*"

Mr. W. ADDISON seconded the motion, which was carried unanimously.

The CHAIRMAN: By the Articles of Association one of the Directors has to retire, but being eligible he offers himself for re-election. I am sure, as Chairman, that it is not possible to find any gentleman who, by his attention to the business and ability to consider what is best for your interests, would equal Mr. Grëwing, and therefore I feel confident that you will not fail to elect him.

Mr. THOMAS LLOYD seconded the motion, which was unanimously passed.

Mr. GRËWING: I thank you very much, gentlemen, for re-electing me.

Mr. ADDISON: I beg to propose—

"*That Messrs. Price, Waterhouse and Co. be and they are hereby re-*" *elected auditors of the Company for the year 1888, and that their remu-*" *neration for that period be the sum of 15 guineas.*"

Mr. J. L. BYLES seconded the motion.

The CHAIRMAN having intimated that that closed the business of the meeting,

A vote of thanks was passed to the Chairman, on the motion of Mr. ADDISON.

The CHAIRMAN: I am very much obliged to you for this vote of thanks, which I accept as due as much to my colleagues as to myself, and probably more so. I am sure that we shall attend in the future to the business before us, and I hope we shall always be able to give you at least as good a report as we are enabled to present you with this time.

The meeting then separated.

CITY NOTES, &c.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of February was 4,528, estimated to produce £3,600, against 3,822 messages, producing £3,009, in the corresponding month of last year. The traffic receipts for the month of November, 1887, estimated at £3,000, realised £2,998.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for February, 1888, amounted to £1,858, against £1,623 in the corresponding period of last year.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company for February amounted to £20,400, from January 1st to February 29th to £41,800, comparing with £39,600 and £38,680 in the corresponding months of 1887 and 1886 respectively.

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this company for the month ended February 29th, 1888, amounted to £4,625.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this company for the week ended March 2nd, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,766.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 513.—Vol. XX. FRIDAY, MARCH 16, 1888. Price 4d.

NOTES.

The effect of the Postmaster-General's announcement disclaiming any intention of purchasing the telephone systems has been rather the reverse of reassuring. In several quarters, chiefly financial, but including some technical journals, the advice given to the companies is to "go ahead," ostensibly in order to enlarge their property so as to increase its value when the time comes for selling it, but really, as it seems to us, to make things so unpleasant all round that the interval between now and the date of sale shall be shortened in spite of Mr. Raikes. The cynical, not to say unscrupulous, language in which this advice is couched ought to make the companies pause before accepting it. In plain words it means simply this—enlarge your capital, and let us all have a share in the good time which is sure to come sooner or later. The companies are even egged on to increase their overhead wires to an insufferable extent, until the public compel the Government to take them under control. All this may be very smart, but it is not business; and our own advice would rather be to go on as if nothing had happened or were going to happen; and, above all, to lay out no money except for money's worth. Depend upon it, whenever the time does come for incorporating the telephone system with the telegraph, the Government will not pay for worthless plant or speculative extensions of the kind recommended. All the same, we consider the situation highly unsatisfactory, and hope that the serious attention of Parliament may soon be directed to it.

The terrible storm which visited the Northern States of America on Monday and Tuesday last will furnish additional, though not fresh, arguments for the adversaries of overhead wires. It is already evident from the imperfect accounts which have yet arrived that the greater portion of the overhead-wire system within reach of the blizzard has been completely destroyed. Our recollection of the condition of the London streets in the early days of last year probably enables us to form only a very faint picture of the spectacle which must now be presented by the streets of New York—and probably, also, of many other towns from Boston to Philadelphia. The occasion is not one, however, for useless reproaches or ill-natured remark of any kind. Our American friends are face to face with a calamity which they have always known to be possible, and which the Board of Aldermen, of New York, have long been endeavouring to avert. Unhappily—and this is where the dilemma arises—notwithstanding the large sums already expended and the rigorous exercise of the powers at their command, the Board have not been very successful in their attempts to solve the difficulty by placing the wires underground. The present disaster will no doubt lead to renewed efforts in this direction, and we still entertain a belief in their ultimate success. Meanwhile our American friends, while re-erecting their overhead lines, will no doubt follow the example set last winter in this country, and take the opportunity to strengthen their supports, increase their struts and stays, and shorten their spans.

Without, however, going to America the English press have taken hold of the comparatively harmless storm which swept over these islands about the same time as New York was being buried in snow and its property destroyed by the wind. Some lines were interrupted for a few hours in the West of England, and in the metropolis, as well as in some provincial towns, several telephone wires came to grief. Accordingly we are again reminded that these abominable contrivances not merely disfigure our streets, which they certainly do, but that they darken the air and decapitate the foot-passengers, which fortunately they do not do. Even by the great storm in the States we hear of no injury to persons inflicted through falling wires.

Our New York Correspondent gives a very interesting summary of the proceedings of the American Electric Light Association, at Pittsburgh. The papers were, as a rule, of the usual practical character, embodying the results of experience in arc and incandescent lighting on a scale which is unhappily quite unapproachable in this country. We would particularly call attention to the excellent paper by Mr. Church (which we reprint in this issue), on the question of engine power. Mr. Church brings forward evidence of a very powerful character in favour of independent engines belted direct to the machines. The question is one of considerable and immediate importance to the electric lighting interest in this country, and if any good reasons can be adduced on the other side we shall be pleased to hear them. The only paper on electric motors was of a somewhat disappointing character. The author dealt chiefly with the theory of motor construction, but as Mr. Reckenzaun pointed out in the discussion his formulæ were not of much practical value. No meeting of this Association would be considered a success without the participation of that learned, witty, and ever-charming scienticulist, Dr. Otto Moses. The Doctor first achieved distinction in the scientific world many years ago by his proposal to employ

Digitized by Google

solidified hydrogen for incandescent lamp filaments. That the brilliancy of the learned doctor's scientific imagination is still undiminished may be gathered from an observation recorded on page 466 of our last issue.

On the whole the account we gave of the reception of Lord Thurlow's Bill in our last week's issue continues to be true, the gas-lighting journals, as well as the political organs, speaking of it in terms which, at all events, are fair if not always friendly. The one exception which has come under our notice is in the pages of *Money*, whose violent abuse and personal insinuations, however, are discounted by the ignorance it displays of the subject under discussion. The arc light is quite as dangerous as gas, according to this authority; and neither the arc nor incandescent lamp is of any use when there is a fog. It is satisfactory to note, nevertheless, that the gas companies are advised to offer their customers the choice of these dangerous and useless means of illumination as against gas—in other words, to take up with the business of electric lighting in order to ward off a competition which is admitted to be dangerous. It is alleged in support of this suggestion that the gas corporations possess already the powers to open up streets, and if they choose "could even run the wires through their existing mains." We are not quite so sure about these powers being applicable to the purposes of supplying electric light, the gas companies, so far as we know, not being exempt from the conditions imposed under the Act of 1882. But we gratefully accept the heroic proposal as, at all events, a testimony to the harmlessness of electric lighting wires, whatever may be said of the lamps. For our part we shall be quite content to let the lamps take care of themselves whenever we have made safe provision for the conductors.

Dr. Oliver Lodge showed a very pretty experiment at the Society of Arts on Saturday last. It is not absolutely new, although many of our readers will probably not have met with it before. When a stick of sealing wax is rubbed on the coat-sleeve and held near a small jet of water which rises to the height of two or three feet, the drops, instead of breaking into fine spray at the summit of the jet, immediately coalesce, and fall almost in a single stream. The effect is very marked, and must be due to the most minute traces of electrical action, since the rubbed wax may be presented two or three feet away from the jet. This experiment may be held to account for the fact that thunder showers usually consist of large drops, but the *modus operandi* is by no means clear. The experiment is, we believe, due originally to Lord Rayleigh.

The lecture was of a most interesting character throughout, and we strongly advise all who have the *entrée* not to miss the second and concluding part, which will be delivered to-morrow afternoon, at 3 o'clock. Dr. Lodge has promised on that occasion to show some new experiments, which will tend to throw light on some of the more obscure phenomena of thunderstorms, and particularly as to the reason why lightning flashes sometimes strike conductors elsewhere than at the top of the rod, and sometimes leave the rod before descending to the earth. The experimental evidence may also be expected to decide the vexed question of iron *versus* copper for lightning conductors. We venture to anticipate a verdict in favour of the latter material.

Our knowledge of electric meteorology, though still lamentably meagre, is certainly making progress. Next week we shall have the Exhibition of Electrical Apparatus by the Royal Meteorological Society. In connection with this display a paper is to be read on the 21st inst., by Mr. G. J. Symons, F.R.S., "On the Non-Existence of Thunderbolts; Elucidated by Accounts of Searches after Them, and the Exhibition of Specimens." It may at first sight sight appear that the argument for the non-existence of thunderbolts will not be greatly strengthened by the exhibition of specimens, but Mr. Symons probably thinks that what is lost in point of consistency is gained in interest, and, perhaps, he only intends to exhibit "reputed" specimens. We do not think, however, that there is any great difficulty in proving the negative, because there are two positive facts which seem amply sufficient to account for the origin of the thunderbolt myth. These are the well-established phenomenon of globular lighting and the entirely independent phenomenon of the fall of meteoric stones.

We understand that negotiations have been opened between the United Telephone Company and the Board of Works which may result in the introduction of a Government Bill for the regulation of overhead wires. The various Metropolitan Vestries have this week been taking counsel together with regard to united opposition to the Telephone Company's Bill.

The Primary Battery—"cheaper than gas"—electric lighting boom still flourishes in perennial vigour. The following is from a leading article in an important provincial journal. After an opening flourish we learn that "Mr. O'Keenan has devised an automatic primary battery, easily portable, which is capable of supplying any number of incandescent lights without waste of any kind. The battery need only occupy a few square feet of space, it is provided with accumulators which store up every particle of electric force not used, and it needs no further attention than that of feeding daily with a scoopful of sulphate of copper. Messrs. Tongue and Birkbeck, who have charge of the patent for this country, assure me that under Mr. O'Keenan's system electric lighting will become little more expensive than gas lighting, and a number of capitalists who have seen the inventor with a view to speculation have expressed themselves highly satisfied with it." We know nothing of Mr. O'Keenan's battery, which may be a highly respectable battery when suitably employed, but we are quite sure that the satisfaction of the capitalists, who have seen the inventor with a view to speculation, will not be of long duration if they plunge in on the faith of the statements advanced in this article. Perhaps, however, it was the inventor who has seen the capitalists "with a view," &c., in which case less harm may be done.

The amount of attention which is now being given to problems connected with alternating currents is very great. In

Digitized by Google

the present issue, in addition to a specially interesting chapter of Dr. FLEMING'S "Notes on Alternate Currents," there will be found a communication of considerable importance from Professors AYRTON and PERRY, on the influence of magnetic lag in transformers. We would also call attention to the remarks which will be found in a review of a pamphlet on a wattmeter designed by Messrs. GANZ and CO. The self-same error therein pointed out has more than once been perpetrated by writers in this country, and arises from an incomplete apprehension of the conditions of a circuit with parallel branches traversed by an alternating current.

WE have examined with much interest the portable reflecting galvanometer and lamp designed by Mr. G. L. ADDENBROOKE, and exhibited by him before the Physical Society last week. The need for a portable reflecting galvanometer which is really reliable and easily set up has long been felt. In Mr. ADDENBROOKE'S instrument these features have been combined in a very ingenious and successful manner. A full description will be found further on.

Manchester.—The Royal Botanical Gardens at Old Trafford are to be lit by electric light during the coming season.

Nancy.—The transformer installation carried out by the Edison Company in this town is now working well, and gives great satisfaction.

The Antilles Cable.—The first section of this cable, between St. Domingo and La Guayra, has been successfully laid, and the section between St. Domingo and Curaçoa is now in hand.

Gorlitz, Austria.—Messrs. Siemens and Co., of Berlin, have tendered for the construction of a central station at Gorlitz. Motive power to the extent of 500 horse-power is to be provided. The total cost is estimated at 625,000fr.

Manchester.—The office of the *Manchester Evening News* is now connected with London by a private wire. This is the first private wire which has been established between the metropolis and the office of a provincial evening newspaper.

Vessels for Sulphuric Acid.—The Benardos process (see *Electrician*, Nov. 25th, 1887) has been applied with success to the coating of thin iron vessels with lead, both inside and outside, in order to contain sulphuric acid. These vessels are said to be cheaper than those at present in use.

The Vevey-Montreux Electric Tramway.—This line which runs alongside the Lake of Geneva, and is about eight miles in length, is now complete. A successful trial trip has just been run over the whole length of the line. The engines are at Montreux, and by means of transformers electric light is provided from the same station.
